GRADING THE GOVERNMENT

Richard W. Parker[*]

For over a decade, scathing critiques of government have been fueled by a group of studies called "regulatory scorecards," which purport to show that the costs of many government regulations vastly outweigh their benefits. One study claims that government regulations cost up to $72 billion per life saved. Another study, co-authored by Bush's regulatory "czar", John Graham, claims that over 60,000 people lose their lives each year due to irrational government regulation. A third scorecard claims that over half of all major regulations issued since 1981 fail cost-benefit tests. These widely cited studies have contributed mightily to a widespread skepticism about the ability of government to regulate rationally. This skepticism has produced, in turn: legislative requirements for more elaborate agency analyses, closer OMB oversight, congressional review of agency decisions, a stream of proposals for further"regulatory reforms" aiming at reining in government agencies, and any number of foregone measures to protect public health, safety and the environment.

But what is the skepticism based on? This Article offers a comprehensive evaluation of the three most influential scorecards behind the "regulatory reform" movement. It demonstrates that all three studies rely on undisclosed data and non-replicable calculations; use biased regulatory samples; misrepresent ex ante guesses about costs and benefits as actual measurements; and grossly under-estimate the value of lives saved, or the number of lives saved, or both. They also exclude all unquantified costs and benefits, disregard all questions about the fairness of the distribution of cost and risk, and conceal the large uncertainties that are present in virtually every regulatory analysis. Close inspection reveals that Graham's sensational claim – that 60,000 lives are lost each year through irrational regulation – is not supported by his study's own data.

This Article also shows that many, though not all, of these defects are endemic to the enterprise of compiling a strictly numerical scorecard, rendering this a defunct mode of analysis. The Article concludes with several affirmative recommendations for improving the assessment of individual rules and government regulation overall.

2

TABLE OF CONTENTS

INTRODUCTION

The Office of Management and Budget estimates that federal government regulation costs businesses or consumers over $500 billion per year.[1] Millions of Americans– as well as many scholars, pundits, think tank analysts, the President, his staff, and a majority or near majority of the House and Senate – believe the costs of these regulations often outweigh their benefits.[2]

The result has been a sustained campaign to try to force agencies to be more "rational": demands for ever more elaborate regulatory impact analyses, closer OMB review of agency regulatory decisions (with more frequent returns), new requirements for congressional review of individual agency decisions, a stream of proposals for further"reforms" to rein in agencies, and an indeterminate number of foregone regulations aimed at protecting public health, safety and the environment.[3]

---

1. See OMB, Draft Report to Congress on the Costs and Benefits of Federal Regulations (2002), 67 Fed. Reg. 15,013, 15,038 (2002). Estimates by leading regulatory critics are even higher. See Clyde Wayne Crews, Jr., Ten Thousand Commandments: An Annual Policymaker's Snapshot of the Federal Regulatory State, 2001 edition, available online at http://www.cei.org/gencon/003,02470.cfm (estimating year 2000 costs at $788 billion); and Hopkins, Regulatory Costs in Profile, Center for the Study of American Business (Now Weidenbaum Center), Policy Study No. 132, Nov. 1996, available online at http://wc.wustl.edu/csab/REG.htm (estimating costs at $688 billion per year).

2. According to a January, 2002 Harris poll, only 33 percent of voters polled expressed a "great deal of confidence in the executive branch of the federal government" – a number which is up sharply from historical (pre-9/11) figures of 17-20 percent – while over half of those surveyed agreed that "we deserve to get better government." Id. See Harris Poll, Jan 16-21, 2002, available online at www.pollingreport.com/institut.htm (visited Feb. 27,2002). The Contract with America devoted an entire chapter to the need to "Roll Back Government Regulations and Create Jobs." Contract with America: The Bold Plan by Rep. Newt Gingrich, Rep. Dick Armey, and the House Republicans to Change the Nation 125-144 (1994). Although the Contract did not pass in its entirety, major regulatory "reforms" did get enacted and countless other reform bills have been, and continue to be, proposed (see sources cited infra note 3). Examples of cost-benefit critiques by policy-makers' and scholars' may be found infra notes 5, 8-10, 13, 15, 16-18, 20-22, 26, 27, and 29.

3. See the 1995 Unfunded Mandates Reform Act, 2 U.S.C. §§ 1501-1571 (2000); the Contract with America Advancement Act of 1996, Pub. L. No. 104-121, enacting the 1996 Small Business Regulatory Enforcement Fairness Act, codified at 5 U.S.C. §§ 601 note (2000) and 5 U.S.C. §§ 801-808 (2000); Government Performance and Results Act of 1993, Pub. L. No. 103-62, codified at 31 U.S.C. 1101 note and 31 U.S.C. 1115 note.

See Ellen Nakashima, For Bush's Regulatory Czar, The Equation is Persuasion, Wash. Post, May 10, 2002, at A35. See also Reluctant Warriors: When it Comes to Deregulation, Bush is no Reagan, Legal Times, Dec. 24, 2001, at 34, ("Graham has already returned more regulations in his first few months in office than the Clinton OIRA did in eight years."); Patrick J. Michaels, Regulatory Overhaul Report Card, Wash. Times, June 10, 2002 (reporting that "Mr. Bush is calling for better scientific analysis, more public involvement in rulemaking, better attention to small business concerns, as well as more aggressive central review - and rejection if need be - of agency rules by OMB.").

For examples of reform proposals driven primarily by cost-benefit critiques, see Hahn, Robert W., and Litan, Robert E., Recommendations for Improving Federal Regulation, Testimony before the Subcomm. On Regulatory Reform and Oversight of the House Comm. On Small Business, June 2002, available online at www.aei-brookings.org. [Hahn 2002a]; Crews, supra note 1; Erin M. Hymel and Laurence H. Whiteman, Regulation: Reining in the Federal Bureaucracy, in Issues 2002: The Candidate's Briefing Book (Heritage Foundation, 2002); Stephen Breyer, Breaking the Vicious Circle: Toward Effective Risk Regulation

4

Although regulatory skepticism is by no means new, the recent wave of regulatory skepticism is distinct from earlier attitudes. If the traditional concern was that agencies would be captured by regulated interests and regulate too little, the modern critique is led by charges that agencies – driven by ideology, bureaucratic ambition or "public interest" pressures – are regulating too strictly and too much. And the cure offered by these critics is not more or better representation in rule-making processes, as in the past, but much more analysis and more searching outside review.[4]

The remarkable ascendancy of the anti-regulatory movement derives from two main empirical sources. One is a stream of well-publicized "horror stories" of government zealotry and caprice: companies forced to clean up Superfund sites to the point where children can eat the soil 245 days a year; air quality regulations issued in total disregard of costs; property owners denied development rights when the footprints of cows were declared wetlands, and so forth.[5]

3. (...continued)
(1993); Richard H. Pildes and Cass R. Sunstein, Reinventing the Regulatory State, 62 U. Chi. L. Rev. 1 (1995); Cass R. Sunstein, Congress, Constitutional Moments, and the Cost-Benefit State, 48 Stan. L. Rev. 247, 257-60 (1996) (arguing that agencies need to better prioritize risks to decide where to regulate); C. Boyden Gray, Obstacles to Regulatory Reform, 1997 U. Chi. Legal F. 1, 1-5; Paul Verkuil, Is Efficient Government an Oxymoron?, 43 Duke L. J. 1221, 1223-34, (1994); W Kip Viscusi, Regulating the Regulators, 63 U. Chi. L. Rev. 1423, 1436-55, (1996); Jeremy D. Fraiberg and Michael J. Trebilcock, Risk Regulation: Technocratic and Democratic Tools for Regulatory Reform, 43 McGill L.J. 835, esp. 835-39 (1998).

Congressional proposals for reform are far too numerous to catalogue. For a few examples, see: The Dole-Johnston Comprehensive Regulatory Reform Act of 1995, S. 343, 104th Cong., 1st Sess. (1995); The Regulatory Improvement Act, S. 981, 105th Cong. (1997); The Regulatory Right-to-Know Act, S.59,106th Cong. (1996); Agency Accountability Act, S. 849, 107th Cong. (2001), (introduced by Sen. Christopher (Kit) Bond, R-Mo.); H.R. 750, 107th Cong. (2001), (introduced by Rep. Sue Kelly, R-N.Y. to require full regulatory impact analysis for regulations impacting small businesses).

4. Professor Shapiro offers an insightful discussion of the rhetorical shift in regulatory criticism from theories of agency capture (which he christens a "reformation) to stories of regulatory over-reach (which he calls a "counter-reformation"). See Sidney A. Shapiro, Administrative Law After the Counter-Reformation: Restoring Faith in Pragmatic Government, 48 U. Kan. L. Rev. 689 (2000). Professor Sunstein discerns three separate strands of regulatory criticism: the agency capture and the contrasting adversarial schools mentioned by Shapiro, and the bureaucratic self-aggrandizement theory of administrative behavior put forward by Niskanen and others. See Cass R. Sunstein, Cost-Benefit Analysis and the Separation of Powers, 23 Ariz. L. Rev. 1267, 1269 (1981). The classic expression of the traditional critique may be found in Grant McConnell, Private Power and American Democracy (1966). Dual critiques – expressing concerns with agency capture by regulated interests *or* public interest groups – may be found in Daniel C. Esty, Toward Optimal Environmental Governance, 74 N.Y.U. L. Rev. 1495, 1515-1518 (1999) (providing an excellent overview of the public choice literature and documenting some egregious cases of regulatory capture - both by industry and environmental groups); Peter Pashigian, Environmental Regulation: Whose Self-Interests are Being Protected?, 23 Econ. Inquiry 551, 573-79 (1985), and William N. Eskridge, Jr., Politics Without Romance: Implications of Public Choice Theory for Statutory Interpretation, 74 Va. L. Rev. 275, 285-90 (1988).

5. The two most famous and influential anecdote-based critiques of regulation have been Philip K. Howard's national best-seller, The Death of Common Sense: How Law is Suffocating America (New York: Random House 1995), and Stephen Breyer's book, Breaking the Vicious Circle, *supra* note 3. The journalist Richard Lacayo reported that Death of Common Sense is "amply stocked with . . . loosely detailed horror stories about

This Article will not have much to say about these stories, except that they need to be treated with caution. Anyone who begins to investigate these stories quickly finds out that some are true; others are exaggerated; many are simply fabricated.[6] Most are published (or repeated) as stories with little or no investigation of the facts. Even if the story turns out to be true, one has no way of knowing whether the incident is typical of agency practice, or an aberration.[7]

The obvious shortcomings of anecdotes as vehicles of proof have given rise to a group of broader studies that have largely supplanted anecdotes as the leading source of regulatory skepticism. These studies have yet to be recognized as a formal genre. I will call them "regulatory scorecards."

Regulatory scorecards are a sub-species of cost-benefit analysis. While the typical cost-benefit analysis devotes hundreds of pages to a narrative describing the costs and benefits of a single project or rule,

---

5. (...continued)
regulatory mischief. Some of them are memorable; some partial or misleading; some flatly wrong." He goes on to rebut several prominent horror stories. Richard Lacayo, Anecdotes Not Antidotes: Philip Howard is Everyone's Favorite Anti-Regulatory Guru, But His Best-selling Book is Flawed, Time, April 10, 1995, at 40. David Mehegan points out that "None [of Howard's anecdotes] is footnoted, so we can't check Howard's facts or assess his interpretations." He also notes that Howard never presents the agency's story. Mehegan, David, Book Review: The Death of Common Sense, Boston Globe, Feb. 14, 1995, at 57. For critiques of Breyer on empirical and conceptual grounds see, see Finkel, Adam M., A Second Opinion on an Environmental Misdiagnosis: The Risky Prescriptions of Breaking the Vicious Circle, 3 N.Y.U. Envt'l L. J. 295 (1995); Sheila Jasanoff, The Dilemmas of Risk Regulation: Review of Breaking the Vicious Circle, 10 Issues in Sci. & Tech. 79 (Spring 1994).

6. For example, the first anecdote cited above has not been rebutted. The second is a mis-statement of law: the Clean Air Act does not rule out cost-consideration in air pollution standard setting, as the Supreme Court made clear in its unanimous decision in Whitman v American Trucking Assoc., Inc., 531 U.S. 457, 463 (2001). The third anecdote is pure fabrication. The "footprints of cows" to which House Majority Leader Tom DeLay referred (in successfully opposing Clean Water Act re-authorization) were not footprints at all, but "wetland sloughs" several feet deep and up to two hundred feet wide which fill with water every year to provide vital sustenance to local and migrating birds. In fact, the land in question is not pasture but a forest which forms a part of the "only [remaining] forest habitat adjacent to the Gulf of Mexico." See Letter of David L. Hankla, Field Supervisor, US Fish and Wildlife Service, to Colonel Robert B. Gatlin, US Army Corps of Engineers, April 19, 1995 [letter on file with author].

For evidence of the broader veracity problem in the regulatory debate see, e.g., Tom Kenworthy, Truth Is Victim in Rules Debate: Facts Don't Burden Some Hill Tales of Regulatory Abuse, Wash. Post, Mar. 19, 1995, at A1 (relating anecdotes that "have the ring of truth, but not the substance"); Jessica Mathews, Horror in the House, Wash. Post, Mar. 5, 1995, at C7; and Citizens for Sensible Safeguards, "Myths and Consequences: Paying for the Use of Myths and Distortions by Anti-Regulatory Zealots," May 17, 1995 (collecting 27 widely-circulating anecdotes about government regulation that are false, exaggerated, or at least factually contested) (unpublished manuscript on file with the author).

7. As Roger Parloff pointed out in his review, "the rhetorical power of The Death of Common Sense derives from the fact that Howard provides only one set of anecdotal horror stories – those that stem from certain unwise laws and regulations, or from unwise applications of them. He never tells the horror stories that prompted all of these laws and regulations." Roger Parloff, The Death of Common Sense – And Its Apotheosis, The American Lawyer 34 (April 1995). See also David A. Wirth and Ellen K. Silbergeld, Book Review: Risky Reform, 95 Colum. L. Rev. 1857, 1884 (noting that Breaking the Vicious Circle "focuses almost exclusively on cases of regulatory overkill . . . while situations that demand more aggressive or rigorous regulatory requirements . . . receive scant attention").

scorecards reduce these hundreds of pages to a few summary statistics – costs, benefits, net benefits and/or cost-per-life saved. Scorecards then tabulate these summary statistics across scores of rules in order to generate what appears to be a concise, precise, and comprehensive picture of the cost-benefit rationality of programs, agencies, and regulations overall.

Three sets of scorecards have been particularly influential in shaping the modern debate over the rationality of the administrative state:

- In 1987, an OMB economist named John Morrall published a table which suggests that federal regulations cost up to $72 *billion* per life saved, and that one-third of the forty-four regulations in his table cost over $100 million for every life saved.[8]

- In 1995, John Graham and Tammy Tengs at the Harvard Center for Risk Analysis co-authored a study, entitled Five-Hundred Life Saving Interventions and their Cost Effectiveness, which reported that regulatory interventions impose wildly disparate costs ranging from less than zero (they save money) to more than a $1 *trillion* per life saved.[9] The least cost-effective interventions, they found, are those aimed at controlling toxins.

  In 1996, these authors published a second study, The Opportunity Costs of Haphazard Social Investments in Life-Saving, which used a computer to see how many additional lives might be saved at constant cost by re-allocating funds among some of the interventions examined in their earlier study.[10] The conclusion: 60,000 additional lives are lost each year by spending money on small or costly risks instead of more cost-effective interventions.[11] John Graham calls this "statistical murder."[12]

- In 2000, Robert Hahn updated his widely-cited 1996 study – Regulatory Reform: What Do the Government's Numbers Tell Us? – with a new study entitled, "Regulatory Reform: Assessing the Government's Numbers." These studies examine over 100 major regulations in what Hahn claims is "the most comprehensive assessment[s] to date of the impact of federal regulatory activities on

the economy."[13]   Both studies reach the same conclusion: though regulations confer a net benefit on society overall, "less than half the rules pass a neutral economist's benefit-cost test" using the government's own numbers.[14]

When three widely-cited studies reach the same dramatic conclusion it should come as no surprise that the impact is enormous. The Morrall table has fueled scathing regulatory critiques by Justice Stephen Breyer, Kip Viscusi, Cass Sunstein, Thomas Hopkins, and others.[15] It has appeared in General Accounting Office reports, in OMB annual reports to Congress, in congressional testimony, in court of appeals opinions, and in the debate over the Contract With America.[16] Law students receive their baptism in the follies of regulation when they encounter the Morrall table in their administrative law and environmental law casebooks and classroom readings.[17] Scientists and aficionados of science confront the lunacy of regulation in two articles in the prestigious journal, Science, in which leading economists (including Nobel-laureate Kenneth Arrow) rely on the Morrall table to argue for more "rational" approaches to regulation.[18]

Scores of newspapers and magazines across America have reported Tengs/Graham's sensational claim that irrational federal regulation is killing over 60,000 people per year.[19] Graham and others have leveled the "statistical murder" charge in testimony before Congress while members of Congress regularly invoke the Tengs/Graham findings in floor debates.[20] The critique has been picked up in scholarly journals,[21] in a leading

committees,[26] and in publications of scholars,[27] think tanks, lobbying organizations and regulatory watch dog groups alike.[28]

Together, these studies have contributed mightily to a climate of opinion in which it seems that the only question of interest is how to accomplish sweeping reforms, not whether the regulatory system needs reforming.[29] Hahn himself has been installed as Director of the prestigious AEI-Brookings Joint Center for Regulatory Studies. Graham has been appointed Director of the Office of Information and Regulatory Affairs (OIRA) at OMB – a position which gives him oversight of all agency regulation. Morrall is a senior official in OIRA. Their world view is now

Niskanen, Regulating by Numbers, in Currents: The CATO Review of Business and Government, No.2, 1996 at http://www.cato.org/pubs/regulation/regv19n2/reg19n2-currents.html.

29. See, e.g., Richard B. Stewart, A New Generation of Environmental Regulation, 29 Cap. U. L. Rev. 21 (2001). One of Stewart's chief charges is that many environmental regulatory programs "entail costs that substantially exceed benefits," Id. at 33, a proposition he supports with a cite to Hahn, Government's Numbers (1996), *supra* note 13, and to Clarence Davies & Jan Mazurek, Pollution Control in the United States: Evaluating the System (1998), which, in turn, relies significantly on the Hahn and Tengs/Graham scorecards. Id. at 135, 137, 140, 141. For a sampling of other reform proposals see Robert Crandall, Christopher de Muth, et al, An Agenda for Federal Regulatory Reform, AEI-Brookings Joint Center for Regulatory Studies, Washington, DC, 1997, available online at www.aei.brookings.org/publications/ books/agenda_for_reg_reform.pdf (last accessed July 8, 2002).

the conventional wisdom, and that wisdom has been built into the law of the land.

But what, exactly, is all this based upon? How solid is the empirical foundation for the anti-regulatory fervor that has gripped Congress, academia and millions of Americans for over a decade?

Only recently have scholars begun to probe these questions. In 1998, Professor Heinzerling published the first critical appraisal of the data and methods behind the Morrall table – eleven years after the table first appeared in print.[30] Since then, Heinzerling also has published critical reviews of the Graham and Tengs studies, though without the benefit of the source data for the Opportunity Cost study (which produced the sixty-thousand-lives claim), since the authors refused to provide her that data.[31] Professor McGarity and Ruth Ruttenberg also have published brief critiques of a number of minor "scorecards" in their important study of the uncertainty of regulatory cost estimates.[32] No one has yet critiqued Hahn's scorecards in a systematic way, though his are the most comprehensive and rigorous of the three, and have circulated widely in the national discourse for almost six years.

This Article builds on the work of Heinzerling, McGarity, and others – along with extensive primary analysis of Hahn's and Tengs/Graham's source data, which this author finally obtained – to provide the first comprehensive and integrated assessment of all three of the leading empirical studies behind the "regulatory reform" movement.[33] It examines the data, the analysis, and a sampling of the primary rules on which each of these scorecards are based, seeking to replicate each scorecard's numbers and to determine what, if anything, the numbers leave out.[34]

---

30. See Mythic Proportions, *supra* note 15. This is not to criticize Heinzerling, who did not even enter the field until long after Morrall's table was published. The point is that *no one* detected the problems with Morrall's table for over a decade, until Heinzerling came along.

31. See, Lisa Heinzerling and Frank Ackerman, The Humbugs of the Anti-Regulatory Movement, 87 Cornell L.Rev. 648 (2002) [hereinafter Humbugs]; Five-Hundred Interventions and Their Misuse, *supra* note 19.

32. Thomas O. McGarity & Ruth Ruttenberg, Counting the Cost of Health, Safety, and Environmental Regulation, 80 Tex. L. Rev. 1997 (2002).

33. Her article, the pathbreaking work on this subject, focused on the Morrall s tudy and did not take issue with the other prominent analyses which come to the same conclusion. Moreover, the scholarly reaction to her critique has tended to focus narrowly on the validity of discounting lives and life values (which she vigorously attacks), thereby obscuring the more basic issues she has raised (and other issues she might have raised) about the validity of scorecards in other respects. See John J. Donohue III, Correspondence: Why We Should Discount the Views of Those Who Discount Discounting, 108 Yale L. J. 1901 (1999). See also Revesz, *supra* note 21. This narrow focus on discounting risks missing the forest for the trees. The principal issue raised by scorecards is not whether discounting is good or bad but whether the scorecards are, overall, reliable litmus tests of regulatory rationality.

34. The goal is not to examine every entry but to audit enough samples to provide a fair picture of how reliable the bookkeeping is. The rules closely examined in this Article were selected to represent a cross-section of agency, subject matter, and numerical result, and to detect and illustrate problems with the methodology employed in scorecard analysis. Thus, rules that generated extreme numbers in scorecards were more likely to be scrutinized

The standards applied in this Article, it should be emphasized, are those embraced by proponents and practitioners of cost-benefit analysis itself. They are not the only standards that might be applied. More than thirty years ago, Professor Laurence Tribe demonstrated that cost-benefit analysis of any stripe necessarily harbors certain assumptions and value judgements which are ideological and contestable: for example, that the litmus test of "rationality" is substantive and objective, not procedural or historical; and that the proximate goal of regulation is to maximize aggregate social utility, with consideration of people's rights relegated to secondary status.[35] His essays contesting such assumptions remain as cogent today as they were three decades ago.

The motive for judging scorecards by the narrow standards of cost-benefit analysis is not to take issue with those who have critiqued this mode of analysis at its core, but simply to give the scorecards the benefit of all possible doubt. Obviously, studies which fail a narrow critique must fail broader and more fundamental tests as well.[36]

How do scorecards fare when judged by the standards of their own professional discipline? This Article will show that they fail badly. Part I reveals that all three studies rely on undisclosed data and non-replicable calculations; use regulatory samples which are biased against a finding of rationality; misrepresent *ex ante* guesses of costs and benefits as actual measurements; and grossly under-estimate the value of lives saved, or the number of lives saved, or both. It turns out that Tengs' and Graham's sensational conclusions are not supported by the authors' own data.

These are the avoidable errors. Part II examines a group of equally serious shortcomings which could not have been avoided because they are inherent in the enterprise of compiling numerical scorecards. First and foremost, regulatory scorecards ignore virtually all benefits that are not quantified and/or monetized – thereby excluding most environmental benefits, many health benefits, and all intangible benefits ranging from the avoidance of pain and suffering or familial and societal disruption to the promotion of a public sense of security, fairness, confidence in markets, etc.

Scorecards ignore the impact of regulations on the distribution of social cost and risk, and the fairness of such impacts.

Finally, scorecards ignore and conceal the large uncertainties that are present in virtually every regulatory impact assessment and that, ironically, is the key to their influence: their use of speciously precise numbers lends

---

34. (...continued)
in this study, but that does not mean that the problems identified in this study are confined to the rules chosen to illustrate them. A flawed methodology applied across the board will generate mistakes across the board.

35. See Laurence H. Tribe, Policy Science: Analysis or Ideology?, 2 Phil. & Pub. Aff. 66 (1972); Laurence H. Tribe, Trial by Mathematics: Precision and Ritual in the Legal Process, 84 Harv. L. Rev. 1329 (1971).

36. Also, for better or worse, cost-benefit analysis (with all its built-in value assumptions) has been ratified by Congress – and applied to regulation – in recent years to a degree that Professor Tribe could not have anticipated when he first issued his critique in 1971. See, e.g, Unfunded Mandates Reform Act of 1995, *supra* note 3. This renders cost-benefit analysis an indisputably relevant test – though not the only test – by which regulations and agency programs may be evaluated.

them a scientific air which impresses the unsuspecting media and the public, but is quite unwarranted by the data.

The shortcomings described above are not merely flaws in the eye of this beholder. When scorecardists disregard ordinal costs and benefits, distributive and equitable impacts and uncertainties, they do so in violation of widely-agreed principles of cost-benefit analysis.[37] Yet this Article also will show that scorecards cannot possibly follow the precepts of responsible cost-benefit analysis while continuing to do the thing that has made them quotable and famous, which is to boil down huge arrays of complex regulatory analyses to a few summary numbers.

Thus, although scholars to date have treated regulatory scorecards as simply another form of cost-benefit analysis,[38] this Article will demonstrate that, in fact, regulatory scorecards represent a distinct sub-species of cost-benefit analysis which inherently violates the basic rules that govern such analysis. Whether or not single-rule cost-benefit analysis is a useful enterprise in practice (an issue on which this Article takes no position), it is clear that numerical scorecards are inherently, and fatally, flawed even when judged by the standards of their own discipline. Scorecards cannot be salvaged. They should simply be abandoned.

Part III addresses the inevitable follow-on question of how government regulatory performance ought to be evaluated, if not by numerical scorecards. This Part argues that the place to begin is with better agency analysis of the costs and benefits of individual rules and regulatory opportunities. Perhaps the most important recommendation in this regard derives from the discovery in Part II that agencies do *not* systematically over-state regulatory benefits, as commonly alleged. On the contrary, agencies often fail to describe benefits fully. Indeed, they often relegate discussion of benefits (particularly non-health benefits) to a few perfunctory sentences in the preambles of final rules. The result is that important benefits often go unnoticed in both scorecards and in the press. Part III thus recommends that agencies take steps to better assess and describe regulatory benefits in the future.

Part III also offers several other suggestions for improving analysis of individual rules, including: correcting obvious (yet long-standing) errors in life and health values; abandoning the pretense that such values are scientifically based; recognizing more clearly and candidly the full range of uncertainties in each analysis; performing many more retrospective studies to validate ex ante estimates, and extending cost-benefit analysis to regulatory opportunities.

At the systemic level, Part III recommends abandoning scorecards as a tool for grading government regulatory performance. Instead, Congress should establish an independent "ombudsman" to investigate alleged regulatory failures (and failures to regulate) one intervention at a time – mixing ordinal and quantitative analysis to produce a full picture of costs, benefits, distributive impacts, and all relevant uncertainties. This labor-intensive inquiry will not yield a numerical "score" for government

---

37. See discussion of these principles *infra* Sections II.A.2, II.B., II.C., and II.D.

38.   See, e.g., Mythic Proportions, *supra* note 15 (treating Morrall table as symptomatic of deficiencies of cost-benefit analysis generally); and Pricing the Priceless: Cost-Benefit Analysis of Environmental Protection (Georgetown Univ. 2001) [hereinafter Pricing the Priceless].

regulation overall. But it will provide what is needed most – an independent and rigorous forum for clarifying, if not resolving, the regulatory controversies that matter most to the public and policy-establishment.

Meanwhile, scholars, policy-makers and the public should be aware that we simply do not know how "efficient" or "rational" government regulation is, from a cost-benefit perspective, because the principal tests that have been used to reach such judgements are invalid.

I. A CRITIQUE OF SCORECARDS: THE AVOIDABLE ERRORS

The last two decades have brought forth a spate of studies which purport to offer rigorous assessments of the rationality of government regulation overall. To begin with, there are studies, like Thomas Hopkins', that dispense with benefits altogether, and merely tote up the costs of regulation.[39] These studies are so uni-dimensional that it is hard to imagine what the authors of such studies think they have proved. Yes, the cost of regulation is high. So is the cost of national defense, the cost of highways, the cost of schools, the cost of the war on drugs, the cost of policemen, the cost of health care, the cost of elections. So what? One cannot arrive at meaningful conclusions about regulation by looking at costs in abstraction from benefits.[40]

Then there are those who look at neither costs nor benefits, but merely count Federal Register pages, and worry that the regulatory burden (i.e. the number of pages in each year's Federal Register) is large and growing.[41] These authors appear never to have read the Federal Register. For simply reading any Federal Register final rulemaking notice would immediately reveal that the vast majority of the pages concerned with regulation are not devoted to setting forth the final rule. They are preambular pages devoted to proposing rules, soliciting comments, explaining the final rule, responding to comments, setting forth analyses of costs and benefits, and so forth. To take an example at random, HHS's final rule on seafood safety occupies 105

---

39. Thomas D. Hopkins, Costs of Regulation: Filling the Gaps. Report prepared for the Regulatory Information Service Center (1992); Thomas D. Hopkins, Cost of Regulation. An RIT Public Policy Working Paper (1991).

40. Similar problems (and others) afflict the annual regulatory cost reports published each year by the Weidenbaum Center (at University of Saint Louis) and the Mercatus Center (at George Mason University), respectively. For a good discussion of the shoddy scholarship found in these studies see McGarity and Ruttenberg, *supra* note 216, at 2016-2020.

41. See, e.g., Mercatus Center Press Release, President Clinton sets record for midnight regulations (Jan. 23, 2001) available online at www.mercatus.org/news/record.html (noting that 25,605 pages of new regulations were published in the Federal Register between Nov. 2000 and Jan. 2001); Angela Antonelli, The Cost of Federal Regulation, Heritage Foundation Press Release (Aug. 4, 1999), available online at www.heritage.org/Press/Commentary/ed080499.htm, (citing the Hopkins study *supra* and worrying that the size of the Federal Register has increased from 53,376 pages in 1988, the last year of the Reagan Administration, to 64,549 in 1997); Clyde Wayne Crews, Regulatory Budget Check (Apr. 1, 2000), available online at www.cei.org/gencon/005,01746.cfm (citing Hopkins' cost estimate after leading with observation that Federal Register contained 71,161 pages in 1999, the highest count since the Carter presidency). These estimates appear oblivious to the fact that many Federal Register have nothing to do with rules, while many that are related to rules are merely explanations of rules or responses to comments.

Federal Register pages. These 105 pages consist of 100 pages of explanation, followed by 5 pages of rule.[42]

Each year since 1997 the Office of Management and Budget (OMB) has published an Annual Report to Congress on the Costs and Benefits of Federal Regulation. OMB generally finds that the monetized *net* benefits of social regulation greatly exceed its costs.[43] As OMB points out, however, the aggregate figures are dominated by a few major rules showing huge net benefits – such as EPA's standards for lead and particulate matter – which may cover a multitude of bad decisions in other areas.[44] Moreover, OMB's analysis of individual regulations does not pretend to capture the non-monetized benefits of regulations, nor does OMB feel free to impose its own subjective opinion as to whether particular rules "pass" or "fail" cost-benefit tests.[45] As a result, OMB's Annual Report does not really serve as a numerical scorecard.

This Part will evaluate the three numerical scorecards that have dominated discussion of regulatory rationality for the last fifteen years: the Morrall, Tengs/Graham and Hahn studies. Section A shows that all three studies rely on undisclosed data, arbitrary adjustments to agency data and non-replicable calculations. Section B demonstrates that all three scorecards employ sampling techniques that are systematically biased against a finding of regulatory rationality. Section C reveals that all three scorecards misrepresent *ex ante* guesses as actual measurements of costs and benefits, and suggests that reliance on pre-rule predictions probably serves to under-estimate net benefits in the majority of cases. Section D shows that Hahn's scorecards systematically under-state the value of lives saved by regulation. Section E shows that Morrall and Tengs/Graham inflate cost-per-life saved by discounting the number of lives saved after a latency period. Section F presents the most surprising discovery of this study: Graham and Tengs' famous (and pessimistic) conclusions about regulation do not follow logically from the authors' own data.

---

42. 60 Fed. Reg. 65,096 - 65,201 (1995). Moreover, there is no correlation between the burden of a rule and its length. While a long rule *may* be burdensome, a rule also may be long because it contains a host of complicated concessions to industry. Indeed, long rules may be passed to *ease* prior burdens on industry. Conversely, Congress could eliminate thousands of pages of text by reducing all environmental obligations to a single sentence: "No one may pollute." Do the page counters think that this would make the environmental laws 99.9999 percent less burdensome?

43. Id. at 11 tbl 2.

44. Id. at tbl 2, where OMB observes: "This benefits estimate is dominated by an EPA estimate that the benefits of air pollution reduction are $1.25 trillion. OMB remains concerned about the plausibility of these estimates." Prior reports make clear that the upper range of EPA benefits estimate derives from EPA's § 812 Retrospective Report, so named because EPA prepared it pursuant to Section 812 of the Clean Air Act Amendments of 1990. See OMB Report to Congress on the Costs and Benefits of Federal Regulation 20 (2000), referring to EPA, The Benefits and Costs of the Clean Air Act: 1970-1990: EPA Report to Congress (1997) [hereinafter § 812 Study]. As EPA notes in the latter report, "a large proportion of the monetized benefits of the historical Clean Air Act derive from reducing two pollutants: lead and particulate matter." Id. at ES-9, ES-7, tbl. ES-4.

45. See *supra* notes 237-239 and accompanying text. Instead, OMB inserts a "Not estimated" entry in the benefits column in such cases, with an explanation in the "Other information" column. See 60 Fed. Reg. at 15,025 tbl 7.

A. *Unreliable data, arbitrary adjustments, non-replicable calculations*

This section applies to regulatory scorecards the most basic test of scholarship: are the data reliable and the results replicable? It will be seen that all three studies fail this basic test. These shortcomings alone would be sufficient to disqualify these studies in any rigorous peer review. Unfortunately, AEI-Brookings, OMB and the Harvard Center for Risk Analysis did not submit these studies to anonymous peer review before publishing them. Thus, there was no screening process to detect the fundamental problems of data and method discussed below.

Morrall. Morrall's table purports to be drawn from agency Regulatory Impact Assessments. Morrall acknowledges, however, that he "sometimes revised" agency estimates.[46] In fact, it appears he alters them by several orders of magnitude in some cases.[47] Morrall justifies these unilateral changes by stating that "regulatory agencies . . . tend to over-state the effectiveness of their actions. Where such biases were evident and easily corrected, I made the corrections . . . [relying in some cases] on published studies."[48]

This easy-going explanation glosses over several acute difficulties. First, Morrall offers no evidence for his claim that agencies systematically over-state the effectiveness of their actions. Indeed, the discussion later in this Article refutes his charge.[49] Second, Morrall has no training in any of disciplines (chemistry, meteorology, toxicology, medicine) which would

---

46. Morrall, *supra* note 8, at 28.

47. For example, as Heinzerling observes, OSHA estimated that its proposed 1985 formaldehyde exposure regulation would save from six to forty-seven lives over forty-five years. Morrall alters that estimate to one life saved every hundred years. In 1986, EPA estimated that its restrictions on land disposal of certain persistent, toxic and bioaccumulative wastes would avert forty cases of cancer, fetal toxicity, reproductive disorders and other ailments associated with chronic toxic exposure per year. Morrall's table translates that to 2.5 lives saved per year – with no explanation of where that number comes from (it is not found in any agency document). In 1983, EPA issued rules to provide for the control and cleanup of radioactive materials at uranium processing sites. Morrall's figure for the lives saved from that rule (2.1) is less than half of EPA's estimate (roughly 5). See Mythic Proportions, *supra* note 15, at 2030.
   Morrall also alters agency cost estimates without acknowledging that he is doing so. His article states, "I generally accepted agency cost estimates without adjustment" and then goes on to explain why he believes there is no need to adjust agency cost numbers. Morrall, *supra* note 8, at 29. Only by independent investigation did the author learn that Morrall substituted his own number of $1.3 billion per year for the agency estimate of $97 million per year as the cost of complying with EPA's rule restricting land disposal of toxic, bioaccumulative wastes. Telephone Interview with John F. Morrall III, Feb. 22, 2002. See Restriction on Land Disposal of California List Wastes: Toxic, Persistent, Bioaccumulative and/or Corrosive, 51 Fed. Reg. 44,714, 44,728 (1984). The calculated cost- per-life saved using the agency's data, without discounting, is $2.38 million. The cost-per-life under Morrall's "adjusted" estimate is $3.5 *billion*. Morrall also increased, by a factor of 20, OSHA's estimate of the cost of its proposed formaldehyde rule. See discussion of formaldehyde rule *infra* notes 164-169 and accompanying text.

48. Morrall, *supra* note 8, at 25, 28-29.

49. See *infra* Section II.A.1. Even where agencies try to quantify benefits, they often tend to under-estimate them. Percival, for example, notes that EPA grossly under-estimated, initially, the risks of lead in gasoline and PCBs. Percival, *supra* note 6, at 182.

qualify him to substitute his own judgement for that of agency scientists on matters of exposure and risk. Third, Morrall does not even name the other studies he allegedly relied upon in generating his own numbers, much less establish their superiority over the agencies' analyses.[50] Finally, Morrall's adjustments and calculations are impossible to verify. His primary data, assumptions and calculations are, by his own admission, "scattered around on yellow legal pads" in his filing cabinets, and are not available.[51]

Morrall is, of course, a government official and a busy man. Scholarship is not his first vocation. The fact remains: his findings cannot be replicated.

Hahn. Hahn claims – in his title and at least 18 times thereafter – that he is just "using the government's numbers" and overtly distinguishes himself from Morrall in this regard.[52] Buried in a few passages laden with technical jargon is the revelation that Hahn makes numerous adjustments to those numbers – usually in the direction of higher costs and lower benefits. For example, he excludes cost savings from regulations because he believes "those savings are generally questionable."[53] He assigns his own values to avoided risks of death or injury, regardless of agency values. He excludes all but a handful of environmental benefits.[54] He discounts cost and benefit streams at his own "standard" discount rates, regardless of agency practice.[55] Costs and benefits that occur before or after 1996 are discounted forward or back to that arbitrary base year – a practice unique to Hahn which (Hahn admits) has a major effect on numerical outcomes.[56] In the many cases in which agencies indicate a range of costs or benefits, Hahn collapses the range and takes only the mid-point, even where the agency has specified a different point in the range as more plausible.[57]

At a minimum, these adjustments call into question the candor of his "government's numbers" claim. Moreover, it has proven difficult (and in

---

50. See Annex A and Morrall *supra* note 8, at 28-29. Despite Morrall's no doubt earnest belief in the superiority of his own judgement, few people outside of OMB are likely to share his confidence that OMB economists know better than agency toxicologists the risks of exposure to PCBs; or that OMB economists are better able than EPA engineers to predict the likely costs of incinerating toxic chemicals in tomorrow's high-tech combustors. In Mythic Proportions, *supra* note 15, at 2027, Heinzerling offers a striking quotation which reveals the frustration felt by OSHA health experts when confronted with the pseudo-expertise of economists like Morrall.

56. Government's Numbers (2000), *supra* note 13, at 45 ("Varying the base year for the present-value calculation significantly affects the magnitude of the estimates.").

57. Id. at 245, no. 9.

some cases impossible) for this author to replicate Hahn's numbers by applying to the numbers set forth in Regulatory Impact Assessments the adjustments he describes.[58]

The result, again, is a highly influential set of numbers which cannot be independently verified.

Tengs/Graham. The Tengs/Graham data are drawn from a wide range of public and private sector documents spanning more than a decade, many of which are unpublished. Their stated criteria for inclusion contain no filter to ensure that the studies they rely upon are of high quality, or even that they are directly comparable.[59]

Moreover, key parameters are calculated in a non-transparent manner which makes replication impossible. One crucial variable, for example, is the estimated percentage implementation of each intervention in the baseline: an intervention deemed capable of saving 50,000 lives at full implementation will save 25,000 additional lives upon re-allocation if the baseline estimate is 50 percent implementation, but no additional lives if the analyst believes that baseline implementation is already 100 percent. Unfortunately, the

---

58. Hahn's published study does not even disclose the *names* of the rules it analyzed. Simply getting the list of rules and the spreadsheet of calculated costs, benefits and net benefits required months of supplication. When Hahn's spreadsheet was finally obtained, it turned out that the adjustments described do not necessarily yield the numbers used. For example, the Coast Guard attributed ecological benefits valued at $230 million to $6 billion, over the period 1991-2015, to its double-hull oil tanker rule. Hahn Spreadsheet for Government's Numbers (2000): Selected Rules, cells CB9, CC9 [unpublished er spreadsheet on file with the author - hereinafter "Hahn spreadsheet"]. Hahn nonetheless assigns the rule a "zero" benefit while claiming he is using the "government's numbers." Id. at cell CF9-CH9. The difficulty of replicating Hahn's numbers is compounded by the fact that he neither publishes his calculations nor includes them within the Excel spreadsheet, as Excel users normally do, but simply uses the spreadsheet as a glorified ledger in which to enter his off-the-record calculations. Nor does he anywhere describe the assumptions he made to derive his "low", "base" and "high" value cost-benefit scenarios. Government's Numbers (2000), *supra* note 13, at 46.

59. The only stated criteria of inclusion are that the study must be in English, examine American experience, and contain separate estimates of full implementation costs and life-saving. See Five-Hundred Interventions, *supra* note 9, at 370.

Spot checks of source documents reveal significant problems in the authors' database and calculations. For example, at least sixteen of the key interventions related to auto safety (accounting for nearly 12,500 additional lives saved in re-allocation) are culled from a single non-peer reviewed NHTSA study which was nearly fifteen years old when Tengs/Graham pulled it out of obscurity in 1995. See Annex B-1, rows 14, 16, 17, 19, 25, 26, 27, 34, 40, 41, 44, 46, 70, 80, 95, 107. See Annex B-1, cell G201, for the calculation of additional lives saved by reallocation to fully fund these interventions. The interventions listed in these rows are not assigned a source, but they match those derived from source no. 175 in Five-Hundred Interventions, *supra* note 9, at 373-375, 385. That source is NHTSA, Office of Traffic Safety Programs, Highway Safety Needs Study: 1981 Update of 1976 Report to Congress (1981) [hereinafter NHTSA Study]. During the period between 1981 and 1995, technology evolved substantially, as did government policies and public attitudes on seat belts, speed limits, and drunk driving. Yet these stale, *ex ante* estimates of hypothetical costs and benefits of various interventions are used as proxies for actual costs and lives saved over a decade later.

This author also discovered a simple arithmetic error in the NHTSA study (the clearly inadvertent omission of a 50 percent fatality reduction effectiveness factor) in calculating lives saved by mandatory seat belt use. This error effectively doubled the NHTSA estimate of lives savable through mandatory seat belt use. Id. at 36. Tengs/Graham pass the error through to their data sheet. See Annex B-1, row 14. This is an isolated incident, but when random sampling turns up errors of this kind, it adds to the impression of a lack of quality control of studies in the database.

authors provide no documentation of how their anonymous reviewers arrived at the conclusion that, as of 1993, the mandatory seat belt use law was "85 percent" implemented, while the public pedestrian safety information campaign was "45 percent implemented" and selected traffic enforcement programs were "78 percent implemented."[60] These numbers have no basis in the source documents – which often predate these estimates by more than a decade – nor is any explanation given of their derivation. Repeated requests for disclosure of the worksheets used to arrive at these numbers were denied. Such omissions and concealments make it impossible to verify the authors' data or replicate their results.[61]

B. *Selection bias*

All three scorecards analyze samples drawn from the larger universe of regulation in order to support broader inferences about that universe. Such inferences are valid only if and to the extent that the samples in question are broadly representative of the population as a whole. This Section demonstrates that all three major scorecards fail this basic condition as well.

Morrall. The forty-four rules that appear in the Morrall table may seem like a lot, but they constitute only a tiny fraction of the regulatory universe. How did these particular rules get chosen to serve as the litmus test of agency rationality? Morrall himself never explains his selection criterion except to note that he included regulations for which "reasonably complete

---

60.   See Annex B-1, rows 14, 17, and 25, respectively. In contrast to their implementation estimates, the authors' data on costs and life-saving can generally be found in the source documents. Not always, however. The authors' data for some important interventions – e.g. oxygen for hypoxemia and flu shots – bear no clear relation to numbers appearing in the source documents. For hypoxemia, the authors estimate that full implementation of the named oxygen therapy would save 45,000 additional lives at an incremental cost of $698 million ($1993), see Annex B-1, row 22, while the source document, S.D. Roberts, Cost-effective Oxygen Therapy, 93 Annals of Internal Med. 499-500 (Sept. 1980), contains no such numbers. The source does observe that "if a half million or so will receive continuous oxygen therapy, the increase in the annual cost of the therapy may be $290 million [equivalent to $509 million in $1993]," and that yearly mortality for continuous oxygen therapy is about 11% and contrasted to 20% for those on nocturnal oxygen therapy. Id. Multiplying 500,000 by the 9% survival differential yields the 45,000 figure used by the author. But the Tengs/Graham cost figure cannot be derived from the source data by any obvious means, and the 500,000 figure itself is not, in any case, an appropriate full implementation number, since the passage just quoted makes clear that the source document author is using 500,000 as an arbitrary benchmark, not as an estimate of full implementation use. Id. Likewise, the flu vaccine numbers used by the authors cannot be found – or derived by any obvious means – in the source documents the authors cite. Compare Annex B-1, row 20, with Office of Technology Assessment, Cost-effectiveness of Influenza Vaccination (Dec. 1981) [unpublished manuscript on file with the author].

61.   The consequences of the authors' casual treatment of implementation rates may be seen in the confusion it created afterwards. Tammy Tengs recently declared that only 20 of the 185 interventions in the Opportunity Costs database were assigned a zero implementation rate in the baseline. Sen. Comm. on Gov. Affairs, Hearing on the Nomination of John D. Graham as Adm'r of the Office of Infl. and Regulatory Affairs at the Office of Management and Budget, 107th Cong. at 8 (2001). Yet the spreadsheet supplied by Tengs to this author lists 40 such interventions. See Annex B-1, column F. Heinzerling has alleged that 79 of the environmental "interventions" in the Opportunity Costs database were never implemented. See Five-Hundred Interventions and Their Misuse, *supra* note 19, at 157-158.

information" on cost and benefit was available.[62] However, as Heinzerling as observed, Morrall omits clearly beneficial final rules for which cost-benefit information was readily available,[63] while including eight rules that were never enacted.[64]   Heinzerling also observes, correctly in this author's view, that the rules included are anything but a random walk down regulatory Wall Street. Of the sixteen EPA regulations on Morrall's list, fourteen have to do with four pollutants – asbestos, benzene, arsenic or radionuclides – which have generated some of the most heated and litigated controversies in all of environmental law.[65] Nowhere does Morrall even attempt to demonstrate that the rules appearing in his table represent a fair sampling of the regulatory universe.[66] Moreover, his focus on proposed or enacted rules (as opposed to regulatory opportunities) introduces a further anti-regulatory bias, as will be seen in the following discussion of Hahn's scorecard.

Hahn. Hahn's scorecard improves on Morrall's by adopting objective selection criterion: all major federal regulations promulgated within a specified period. Hahn, however, follows OMB in defining "major rules" as those that cost more than $100 million per year to comply with. This filter effectively excludes from the database the most cost-effective interventions of all: interventions which yield (or would, if adopted, yield) major benefits without imposing major costs. The result is an in-built sampling bias against regulation.[67]

An equal or greater source of bias is found in the fact that both Morrall and Hahn focus on rules, actual or proposed.   They choose not to examine rules that were never issued but would be cost-effective if they had been. This is a serious shortcoming. Basic environmental economics teaches that efficient resource allocation requires internalizing externalities (through regulation, Pigouvian taxes or marketable permits) in all cases where significant externalities arise.[68] This means that under-regulation can be just

---

62. Morrall, *supra* note 8, at 27.

63. She cites EPA's phase-down of lead in gasoline and its regulations controlling common air pollutants as examples. Mythic Proportions, *supra* note 15, at 2016.

64. Id.

65. See, e.g., cases and controversies collected *infra* note 71.

66. As Heinzerling notes, the cost-ineffective "bottom" of the Morrall table is heavily stocked with regulations that he and others at OMB had heavily criticized. Mythic Proportions, *supra* note 15, at 2015.

67.   The "major rule" selection criterion also filters out minor rules that are not subject to OMB review and detailed agency cost-benefit analysis. If such rules are systematically less cost-effective than major rules (a point which has not been established empirically) the result would be a contrary skew towards a higher grade for government regulation. It is thus difficult to determine, in Hahn's case, the direction of the selection bias, much less the magnitude. There is no reason to assume, however, that opposing sources of bias simply cancel each other.

68.   See Maureen L Cropper and Wallace E. Oates, Environmental Economics: A Survey, 30 J. of Econ. Lit. 675, 681 ("The basic theoretical result . . . is that the efficient resolution of environmental externalities calls for polluting agents to face a cost at the
(continued...)

as inefficient – in the sense of producing a misallocation of resources – as over-regulation. By systematically excluding all cases of under-regulation, Hahn and Morrall introduce yet a further skew towards a finding of over-regulation.

Tengs/Graham. Tengs/Graham avoid this skew by examining regulatory opportunities as well as implemented regulations. They also avoid problems of subjective sampling by defining their sample in objective terms: (1) A life-saving intervention must be analyzed in written study. (2) The study must be in English. (3) The study must be about American experience. And (4) the study must be supported by an estimate of full implementation cost and full-implementation lives saved.

Unfortunately, this approach solves certain problems of bias only by creating others. As the authors acknowledge, their "data set may not represent a random sampling of all life-saving interventions . . . because . . . those economic analyses that researchers have chosen to publish may be disproportionately expensive or inexpensive."[69] It is extreme results, after all, that are typically deemed most interesting and publishable. Moreover, authors who choose to publish estimates of full-implementation costs and benefits, as opposed to actual costs and benefits, likely do so because they have concluded that full implementation is either quite a good idea or quite a bad one. The bias towards extremes in sampling yields a corollary bias in favor of greater life-saving through re-allocation.[70]

In practice, Tengs/Graham's publication bias appears to have generated a sampling distortion that operates much like Morrall's selection bias. For example, anyone familiar with environmental policy will immediately recognize that the toxin control portion of the Tengs/Graham sample (comprising more than half of the 185 interventions in the sample) is dominated by just seven substances – asbestos, arsenic, benzene, ozone, radionuclides/radon, and vinyl chloride – which have generated some of the most contentious disputes in all of environmental law.[71] There is no reason

---

68. (...continued)
margin for their polluting activities equal to the value of the damages they produce . . .").

69. Five Hundred Interventions, *supra* note 9, at 372.

70. Indeed, as seen *supra* note 60 and accompanying text, even the numbers for baseline costs and lives-saved were generating not by looking directly at actual costs and lives, but by multiplying full implementation costs and lives by reviewers' estimates of the "percent implementation" of the program. For the 104 programs implemented at either zero or 100 percent in the baseline scenario, this is not a source of error. But for the remaining 82 programs, the indirect approach produces a needlessly inexact estimate of costs and lives saved in the baseline.

71. See, e.g, Corrosion Proof Fittings v. EPA, 947 F.2d 1201 (5th Cir. 1991) (striking down EPA's comprehensive asbestos ban); Columbia Falls Aluminum Co. v. EPA, 139 F.3d 914 (1998) (holding that EPA's use of an inaccurate predictor of toxic mobility in promulgating a rule regulating the concentrations of, inter alia, arsenic was arbitrary and capricious); Leather Indus. of Am. v. EPA, 40 F.3d 392 (1994) (upholding in part a challenge to EPA's regulation of heavy metal sludge contaminants, including arsenic); National Resources Defense Council v. EPA, 824 F.2d 1146 (D.C. Cir. 1987) (remanding a vinyl chloride emissions standard to EPA for failing to evaluate the standard's estimated affect on people's health); Indust. Union Dept., AFL-CIO v. Amer. Petroleum Inst., 448 U.S. 607 (1980) (holding that the Secretary of Labor is required under the Occupational Health and Safety Act to issue a benzene emission standard only after making an initial inquiry to

to assume that the saga of efforts to regulate these seven chemicals typifies the experience of the thousands of pesticides and other toxic chemicals that EPA and OSHA routinely oversee in the marketplace.[72] Yet these seven substances account for more than 90 of the 98 toxin control interventions, and 99 percent of the toxin control baseline costs in the sample.[73]

What would have been the right approach to regulatory sampling? Clearly, the database should have included either a comprehensive review or, more likely, a truly random sample of major and minor rules and rule candidates. While finding a proper method for sampling rule candidates is obviously a difficult enterprise,[74] this does not excuse biased regulatory sampling. Whatever the reasons for the bias, the fact remains that scorecards based on non-random and biased sampling do not support broad inferences about the rationality of regulation overall.

---

71. (...continued)
confirm that the standard is "reasonably necessary or appropriate" and the substance being regulated can cause a "material health risk." 448 U.S. at 614-15.); Whitman v. American Trucking Assoc., Inc., 531 U.S. 457 (2001) (ozone); Sierra Club v. EPA, 107 F.3d 923 (1996) (upholding EPA's decision to permit NRC to regulate radionuclide emissions from nuclear reactors as not unreasonable).

For insights into the controversy over the Bush Administration's recent decision to suspend the Clinton EPA's regulation on arsenic in drinking water, see Cass R. Sunstein, The Arithmetic of Arsenic, 90 Geo. L. J. 2255 (2002); Thomas O. McGarity, Professor Sunstein's Fuzzy Math, 90 Geo. L. J. 2341 (2002); and Lisa Heinzerling, Markets for Arsenic, 90 Geo. L. J. 2311 (2002). For the dispute over radon regulation see, Gina Kolata, How Much Radiation is Too Much?, N.Y. Times, Nov. 27, 2001, at F1; and Robert W. Hahn and Jason K. Burnett, The EPA' Radon Rule: A Case Study in How Not to Regulate Risks, AEI-Brookings Joint Center for Regulatory Studies: Regulatory Analysis 01-01, Jan. 2001, available at www.aei.brookings.org/publications/ reganalyses/ reg_analysis_01_01.pdf.

72. Focusing obsessively on seven atypical substances may be thought to over-state the costs of regulation, in view of the fact that these substances have been so controversial and hotly litigated on grounds of cost. On the other hand, the relative efficiency of actual spending on these substances may reflect the impact of searching judicial review which has restrained agencies from regulating some of these substances as stringently as they would like. For example, the Corrosion Proof Fittings decision may have restrained EPA from imposing high costs to phase out asbestos in all uses. See Corrosion Proof Fittings v. EPA, 947 F.2d 1201 (5th Cir. 1991). This makes it impossible to determine the magnitude, and even the direction, of the bias in sampling of toxics. But that just deepens the quandary created by their sampling methods. All that one say with confidence is that the toxic control interventions that appear in the Tengs/Graham studies are not representative of toxic regulation overall. Indeed, Heinzerling points out that 31 of the 90 environmental measures in the Tengs/Graham database were undertaken (or not) under statutory provisions [Section 6 of the Toxic Substances Control Act] that has been effectively defunct for over a decade. See Five-Hundred Interventions and Their Misuse, *supra* note 19, at 161.

73. Significantly, Hahn and Morrall would have treated these ninety-eight interventions as just eight interventions since they appear in only eight rules.

74. Relying exclusively on the published literature does not work, for the reasons described above. A better approach might have been to convene an inter-agency (or non-governmental) task force analogous to the EPA working group that Administrator Lee Thomas convened in 1986-87 with a mandate to survey the universe of rules and regulatory opportunities as a aid to setting priorities for future regulation. See EPA, Unfinished Business: A Comparative Assessment of Environmental Problems, Vol.1. at 21 (1987) [hereinafter Unfinished Business] (unpublished manuscript on file with the author).

C.   *The ex ante fallacy*

Every year footballs pundits on pre-game shows take turns guessing the score or the point spread of the Super Bowl that is soon to follow. But then the game happens, and newspapers report the results of the game. Fortunately, there is no record of any occasion in recent history when a newspaper has committed the blunder of confusing the pre-game guesses with the actual score of the game.

Yet this sort of blunder is virtually universal in scorecards where conclusions are routinely described as if they represent actual measurements of costs and benefits when, in fact, the numbers consist exclusively of analysts' educated guesses about what future costs and benefits might be in a variety of hypothetical scenarios.

For example, Graham and Tengs report that "the annual resources consumed by those interventions total approximately $21.4 billion. For such a sum, we avert approximately 56,700 premature deaths and save 592,000 years of life annually."[75] In fact, the baseline and re-allocation numbers for all but nine of the interventions that affect the Opportunity Costs results are derived exclusively from *ex ante* guesses about cost or lives saved in a hypothetical full implementation scenario.[76]   Moreover, many of those estimates were already more than a decade old by the time the Tengs/Graham study was published.[77] By relying on aged guess-timates, Graham and Tengs ignore, in these cases, ten to twenty years of actual experience.

Morrall and Hahn likewise describe their findings as actual costs and benefits when, in fact, Morrall and Hahn derive their data exclusively from regulatory impact statements issued long before the rule in question took effect.[78]

Confusing predictions with actual results has two deleterious effects. First, it creates a bogus appearance of precision which renders the scorecards highly quotable – and fundamentally misleading.[79] Second, *ex ante*

---

75.   Opportunity Costs, *supra* note 10, at 172.

76.   See Annex B2-a (rows below row 114 that are 100 percent implemented in baseline and are zeroed out in re-allocation).

77.   See Five-Hundred Interventions, *supra* note 9, Appendix A and Appendix B (listing sources for cost-per-life estimates used in both that and the smaller Opportunity Costs study). For example, the numbers for 12 traffic safety education interventions come from a 1981 study (No. 175 in Tengs/Graham's database) which draws on data from the Seventies. The numbers for the life-saving potential of universal influenza vaccination come a 1981 study.   Office of Technology Assessment, Cost Effectiveness of Influenza Vaccination (Dec. 1981) (unpublished manuscript on file with the author). The huge life-saving potential of nocturnal oxygen for hypoxemia patients (which saves 23,000 additional lives in the re-allocation scenario) derives from a two-page editorial published in a medical journal in 1980. S.D. Roberts, Cost-Effective Oxygen Therapy, 93 Annals Intern. Med. 499-500 (1980). The numbers for 11 interventions relating to pollution control at paper mills were drawn from a 1990 study (No. 844) which was itself a study of EPA assessments made during the Seventies and early-Eighties. See R.A. Luken, Studies in Risk & Uncertainty 10-11 (1990) (describing age of sources).

78.   See Morrall, *supra* note 8, at 25, 27; and Government's Numbers (2000), *supra* note 13, at 32, 38.

79.   Of course, *ex ante* estimates may serve as relevant indicators of decision

(continued...)

predictions likely to under-state net benefits in many cases. The reason is not, as commonly believed, that costs of any given policy are necessarily over-estimated or benefits under-estimated in agency assessments.[80] The reason is found in the static nature of cost-benefit estimation.

Cost-benefit calculations made in the course of rule-making or rule advocacy are snapshots of a hypothetical future. They generally assume the policy will be applied without adjustment for the duration of the planning period. This assumption makes reasonably goods sense when applied to the evaluation of specific projects – like dams, roads and commercial developments – which are essentially irreversible once installed.[81] Most regulations, by contrast, may easily be modified, eased by waivers, sub-categories and variances, or repealed at some future time. These dynamic feedback loops allow regulators to adjust the impact of regulations, as applied, so that high net benefit regulations stay in place, while low or negative net benefit regulations are either repealed, modified, or eased by variances.

Predictions which ignore dynamic policy adaptation will tend to under-state the net benefits of regulation. To take just one example, EPA's Final Great Lakes Water Quality Guidance aims to curtail emissions of persistent,

---

79. (...continued)
rationality if all understand that the latter is being judged solely by the facts available to the agency at the time it made its decision. See Citizens to Preserve Overton Park v. Volpe, 401 US 402 (1971) (establishing this as the standard for judicial review of agency rules). The problem with this standard is that the facts available to the agency during rulemaking normally do not permit it anticipate how often (and in what cases) waivers and variances, rule modification and enforcement discretion will be used to reduce unexpected regulatory burdens. See discussion later in this Section.

80. Some authors point out, correctly, that hard-to-quantify benefits tend to be under-stated in agency cost-benefit estimates. McGarity, Thomas O., Reinventing Rationality: The Role of Regulatory Analysis in the Federal Bureaucracy 131 (1996) [hereinafter Reinventing Rationality]. Others point out, equally correctly, that agencies tend to over-estimate those benefits that they do quantify when they adopt conservative risk assumptions in evaluating proposed regulations. Morrall, *supra* note 8, at 29; Albert L. Nichols & Richard J. Zeckhauser, The Perils of Prudence: How Conservative Risk Assessment Distorts Regulation, Regulation 13 (Nov./Dec. 1986). The *net* effect of these opposing biases may well depend on the facts of each case. On the cost side, analysts likewise disagree on whether the costs of any given policy tend to be under-stated or over-stated. See discussion *infra* Section II.A.f. One of the few actual comparisons of cost predictions with actual experience suggests that *ex ante* cost estimates are sometimes under-stated, sometimes over-stated, and sometimes about right. Winston Harrington, Richard D. Morgenstern, Peter Nelson, On the Accuracy of Regulatory Cost Estimates, Discussion Paper 99-18, 2 (Jan. 1999), available online at http://www.rff.org/CFDOCS/ disc_papers/PDF_files/9918.pdf (visited Sept. 4, 2002). See also William D. Nordhaus, From Porcopolis to Carbopolis: The Evolution from Pork Bellies to Emissions Trading, in Richard F. Kosobud (ed.), Emissions Trading: Environmental Policy's New Approach 61, 66 (noting that while sulfur dioxide reduction costs were over-estimated, chloroflourocarbon control costs were, if anything, under-estimated).

81. One might, of course, ease the impact of a dam by installing fish ladders or controlling water flow in various ways. This is tinkering around the edges, however. Generally speaking, the costs and benefits of a dam are what they are, once the dam is built, and there is not much (short of blowing up the dam) that future decision-makers can do about it.

bio-accumulative toxic pollutants into the Great Lakes.[82] EPA anticipated an annualized compliance cost of between \$60 and \$380 million per year (\$1994).[83] But EPA also said that it expected actual costs to be near the low end of the range because final decision authority for implementing the Guidance was being delegated to States and Tribes who would retain discretion to provide waivers and variances in cases where strict compliance would impose excessive costs.[84] Yet Hahn's scorecard ignores this corrective mechanism. It mechanically adopts the mid-point estimate of \$218 million, thereby assuming that EPA will rigidly apply its rules in many cases, even when EPA has expressly stated its intention *not* to do that.[85]

In theory, the auto-pilot fallacy might be avoided by confining the database to retrospective cost-benefit studies. These, however, are few and far between, for two reasons which McGarity and Ruttenberg have well explained in a recent article.[86] First, retrospective analyses are surprisingly difficult: causal connections between regulation and impact are hard to establish, in practice, and even retrospective studies require a counter-factual and hypothetical analysis of what the world would have been like absent the regulation. Second, agencies have little or no incentive to probe, in detail, the possibility of their own prior analytical mistakes.[87] The result is a dearth of retrospective studies which forces scorecardists to rely on *ex ante* guesses about regulatory costs and benefits. This in no way justifies, however, the current practice of reporting such guesses as if they were actual costs and benefits – thereby grossly over-stating the reliability of the figures and, probably, under-stating net benefits.

D.   *Undervaluing life and health benefits (Hahn)*

---

82.   Final Water Quality Guidance for the Great Lakes System, 60 Fed. Reg. 15,336 (1995).

83.   Id. at 15,381.

84.   Id.

85.   See Annex c, Row 70. The cost number listed in the seventh column, \$2,764 million, represents the present value of a 20-year stream of costs which, according to Hahn's spreadsheet, are assumed to be \$218 million annually. The \$218 million figure is stated as the assumed annual cost in cell AH-9 of the spreadsheet, on file with the author.

86.   McGarity and Ruttenberg, *supra* note 216, at 2040.

87.   McGarity and Ruttenbergy recall: "As one candid EPA regulatory analyst asked rhetorically in an interview conducted almost two decades ago, 'How is my career going to be advanced by doing a study that shows that three years ago the agency made a wrong prediction?'" Id. at 137. See also Harrington, *supra* note 67 at 2 ("ex post studies of the cost of regulation are quite scarce").
The most comprehensive such analysis is unquestionably EPA's seven-year retrospective study of the costs and benefits of the Clean Air Act, mandated by Section 812 of the Clean Air Act Amendments of 1990. See § 812 Study, *supra* note 87. However, that study does not examine costs and benefits at the level of individual regulations, and therefore sheds no light on the accuracy of *ex ante* Regulatory Impact Assessments. One study that directly compared *ex ante* and ex post regulatory cost estimates found that *ex ante* estimates exceeded actual costs for 12 rules, under-estimated costs for 6 rules, and were roughly accurate for the remaining 7 rules. Harrington et al, *supra*.

Hahn, as we have seen, assigns a "standard" value of $5 million per statistical life saved, with $3 million and $7 million values used in sensitivity analysis. He then discounts the value of lives saved in the future – for example, after a latency period following exposure to a carcinogen – at five percent per year.[88]

Such practices are now commonplace in agency analysis as well.[89] Some scholars have objected on ethical grounds to the practice of monetizing, and then discounting, the value of reducing risk to human life.[90] Others have defended the inevitability of the first and the propriety of the second.[91] Rather than re-open that argument, the discussion that follows assumes that regulators will go on monetizing and discounting for the foreseeable future.[92] This section simply argues, building on the work of Professor Revesz and others, that the risk-to-life-values in current use are not empirically well-grounded, and are far too low by their own interior logic.[93]

The problems discussed in this section arise ultimately from the fact that politicians and regulators are loathe to be seen assigning a finite value to even limited risks to human life as an express policy choice. Instead, they try to deflect political accountability by pretending that the values so assigned are derived by neutral, scientific means directly from the wishes of the electorate itself. The hollowness of this pretense becomes apparent, however, as soon as one takes a close and critical look at the actual studies from which these numbers emerge.

---

88. Government's Numbers (2000), *supra* note 13, at 39.

89. See, e.g., OMB, Guidelines to Standardize Measures of Costs and Benefits and the Format of Accounting Statements: Memorandum for the Heads of Departments and Agencies from Jacob J. Lew, Director, M-00-08, at 6 (March 22, 2000) [hereinafter: OMB Guidelines] (calling on agencies to "monetize quantitative estimates [of costs and benefits] whenever possible," to "discount [monetized] benefits and costs that occur in different time periods" and to "provide a clear explanation of the rationale behind any regulatory choice that is based on unquantifiable benefits or costs"); and OMB, 2001 Discount Rates for OMB Circular No. A-94: Memorandum for the Heads of Departments and Agencies from Mitchell E. Daniels, Jr., M-01-14 (March 7, 2001)(prescribing a 3 percent real interest rate for long-term cost-effectiveness analysis). While OMB has not required that agencies all use the same life value, agencies typically assign life saving a value of less than $7 million. See OMB Guidelines, *supra*, at 12-13 (reviewing agency life value assumptions).

90. See, e.g., Mythic Proportions, *supra* note 15, at 2042-2056; Pricing the Priceless, *supra* note 38, at 11-16; Lisa Heinzerling, The Rights of Statistical People, 24 Harv. Envtl. L. Rev. 189 (2000) [hereinafter Rights of Statistical People].

91. See, e.g., Donohue, *supra* note 33; Morrall, *supra* note 8, at 28-29.

92. The standard answer to arguments that risk to life should not be assigned a monetary value is that society implicitly assigns such a value every time it chooses to tolerate any risk at all. Regarding life as infinitely valuable would require attempting to eliminate every conceivable risk to life no matter how minute or costly to avoid – a policy which would impoverish society so much that few people, if any, would choose it. Compare Pricing the Priceless, *supra* note 38, at 11-16, with Fatal Trade-offs, *supra* note 15, at 3-5.

93. Revesz, *supra* note 21, at 962-987 (criticizing simple extrapolations from labor market studies); Cass R. Sunstein, Daniel Kahneman, David Schkade, Ilana Ritov, Predictably Incoherent Judgments, 54 Stan. L.Rev. 1153, 1196-1197; (criticizing contingent valuation techniques); and Peter A. Diamond & Jerry A. Hausman, Contingent Valuation: Is Some Number Better than No Number?, 8 J. Econ. Persp. 45 (1994).

Briefly, Hahn draws his risk-to-life values from a collection of contingent valuation and labor market studies which are largely the same studies on which EPA and other agencies also rely.[94] Contingent valuation studies, as many scholars have pointed out, elicit hypothetical answers to hypothetical questions, with no way to verify that such polls measure people's real values.[95] Such studies are inherently unreliable.

Labor-market studies, on the other hand, observe actual market behavior in the form of wage-premiums accepted by workers in high risk jobs: the yearly wage-risk premium divided by annual job risk yields the implicit value of risk-to-life accepted by these workers. Despite the advantage of having access to actual behavior, labor market studies exhibit several drawbacks of their own, particularly when they are used to try to value risk in other, quite different social contexts:

1. Existing labor market studies employ different data, methods, assumptions and models to yield a wide range of implicit life values, extending from less than $1 million to nearly $18 million, measured in 2000 dollars.[96] None of these studies has been quality-controlled to a level remotely commensurate with the weight they now carry. Neither Hahn nor the agencies who rely on these studies have supplied any convincing explanation of why they chose to rely on particular studies, why the life values yielded by existing studies vary by more than an order of magnitude, and why one value (or range of values) was chosen rather than another.[97]

---

94. Specifically, he says "I used standard willingness-to-pay estimates based on labor market studies of risk dollar tradeoffs for fatal and nonfatal risks." Government's Numbers (2000), *supra* note 13, at 39, n.24, citing W. Kip Viscusi, The Value of Risks to Life and Health, 31 J. Econ. Lit. 1912 (1993) [hereinafter Value of Risks to Life], which presents the same results as Viscusi's book, Fatal Tradeoffs, *supra* note 15.

95. This is only one of the many serious problems that plague contingent valuation studies. For a trenchant critique by a Nobel-laureate economist raising issues unanswered by defenders of the practice, see Amartya Sen, Cost-Benefit Analysis: Legal, Economic and Philosophical Perspectives: Remarks to a Conference Sponsored by the John M. Olin Foundation and the Univ. of Chicago Law School, 29 J. Legal Stud. 931 (2000).

96. Fatal Tradeoffs, *supra* note 15, at 52-53 tbl 4-1; EPA Guidelines for Preparing Economic Analysis, EPA 240-R-00-003, 89 Exh. 7-3 (2000) [hereinafter EPA EA Guidelines].

97. EPA makes no distinction among the studies in its database. It simply takes the "central tendency" of these studies while noting that "Further research on synthesizing the results of these studies . . . may provide better estimates." EPA EA Guidelines, *supra* note 96, at 90. The Department of Transportation, which houses the Federal Aviation Administration and the National Highway Traffic Safety Administration, has chosen a life value of $3.0 million ($2002) with no public discussion. See Memorandum from Kirk K. Van Tine to Assistant Secretaries, Revised Departmental Guidance on Treatment of Value of Life and Injuries in Preparing Economic Valuations, January 29, 2002 [unpublished memorandum on file with the author) ("To deepen understanding of the empirical basis for these values . . . we are initiating a process of consultation within the department . . . we intend to invite experts in this field of research to meet informally with DOT staff . . ."). Viscusi offers a limited methodological evaluation of these studies in Fatal Tradeoffs, *supra* note 15, at 51-59, but his discussion does not really narrow the range through a rigorous evaluative process. He notes that "most of the reasonable estimates of the value of life are clustered in the $3 to $7 million range," Id. at 73, when, in fact, more than half of the values in his own table fall outside that range. Id. at 52-53 tbl 4-1. Other scholars have performed meta-analyses which try, in various ways, to control for quality and adjust for differences

(continued...)

Nor have agencies opened their deliberations on this matter to public involvement. Herein lies both a problem and an irony. Whereas individual rules are made with extensive public participation and detailed analysis, the fundamental parameters that agencies employ in assessing a vast range of rules – rules that affect the lives, the health and the safety of tens of millions of Americans – are derived with little explanation and no public process at all.[98]

2. Labor market studies do not demonstrate that the workers in the database enjoy a free and unfettered choice of jobs with various risks, and that they accurately assess the risks of the jobs they are taking.[99] This raises serious doubt as to whether current studies measure the true willingness of these workers to accept compensation for risk on the job.

3. Even if such studies accurately measure workplace wage-risk premiums, workplace risks are not the sort of risks that matter to most social regulation.[100] The former are discrete, controllable (to some extent) and voluntary. The latter are generally cumulative, uncontrollable and involuntary. Most scholars agree that involuntary risks should be valued more highly than voluntary ones: some say twice as high.[101] Likewise, it seems clear that cumulative risks – the sort of risks that result when agencies apply a value-of-life rule-of-thumb to multiple agency decisions – should be

---

97.   (...continued)
among methods, assumptions, and databases. See, e.g., Janusz R. Mrozek and Laura O. Taylor, What Determines the Value of Life?: A Meta-Analysis, 21 J. Pol'y Analysis and Mgmt. 252 (2002); and T. Miller, The plausible range for the value of life -- red herrings among the mackerel. 3 J. Forensic Econ.17 (1990). But this, without more, simply adds a new dimension of uncertainty about the assumptions and methods of the meta-analyses.

98.   See Valuing Risks to Life, *supra* note 93.

99.   Fatal Tradeoffs, *supra* note 15, at 38. Even if workers accurately estimate the risks they are assuming, labor market studies supply no evidence that high-risk workers enjoy ready access to less risky job alternatives, as necessary to permit the inference that the wage premia reflect a voluntary decision. See Sidney A. Shapiro & Robert L. Glicksman, Risk Regulation at Risk: Restoring a Pragmatic Approach 98-100 (2003); and Reinventing Rationality, *supra* note 80, at 147-148.

100.   Occupational Health and Safety Administration (OSHA) regulations being the obvious exception.

101.   See Maureen L . Cropper & Wallace E. Oates, Environmental Economics: A Survey, 30 J. Econ. Lit. 675, 714 (1992) (citing studies showing that voluntary risks and involuntary risks are valued differently). Revesz has found survey evidence which suggests that people value avoidance of "dread" risks like cancer twice as dearly as avoiding sudden accident risks. See Revesz, *supra* note 21, at 972. I do not incorporate an explicit adjustment for the dread factor because I suspect it that it overlaps to a considerable degree with involuntariness (i.e., people polled about their attitudes to cancer probably assume involuntary exposure). If so, combining dread and involuntariness. adjustments multiplicatively would significantly over-state risk-to-life values.

valued more highly than isolated risks.[102] Current life values fail to reflect either of these crucial distinctions.

4.   High-risk jobs select for risk-tolerant workers, which means that wage premiums for these jobs understate the average American's risk aversion.[103] Current life values incorporate no adjustment to reflect this difference.[104]

5. It is widely agreed that wealthier people will demand more money, *ceterus paribus*, to accept a non-pleasurable risk than poorer people, because wealthier people get less marginal utility from each incremental dollar.[105] Yet current life values make no adjustment to reflect the fact that (a) the median American earns a third more than the typical high-risk worker;[106] (b) real incomes have grown 2 percent per year, on average, for twenty years since the date of the data (1982) used in the most recent labor market studies on which agencies currently rely;[107] and (3) real incomes will likely continue

---

102.   As Sen and others have noted, the most plausible individual utility function is not linear, but concave, meaning that increasing increments (or cumulations) of risk are associated with supra-linear disutility. Sen, *supra* note 85, at 938. If so, any life value that accurately measures the benefit of avoiding small risks at the margin, will understate the cumulative benefit of avoiding multiple risks. See also Viscusi, Value of Risks to Life, *supra* note 94, at 1938.

103.   Viscusi, Value of Risks to Life, *supra* note 94, at 1938 ("The usual studies of a single risk-wage tradeoff . . . ignore the substantial heterogeneity across individuals in their attitudes toward risk."); Mrozek, *supra* note 97, at 264 (2002) (finding self-selection effects dominant at very high risk jobs).

104.   See Steven Kelman, Cost-Benefit Analysis and Environmental, Safety, and Health Regulation: Ethical and Philosophical Considerations, in Cost-Benefit Analysis and Environmental Regulations: Politics, Ethics, and Methods 144 (D. Swartzmann et al. eds, 1982), cited in Reinventing Rationality, *supra* note 80, at 148.

105.   Value of Risks to Life, *supra* note 94, at 1930. The rate at which risk-to-life value rises with income is known as the "income elasticity" of the value: an elasticity of 1.0 means that a 20 percent increase in risk produces a 20 percent increase in measured life value. The existing literature has spawned a range of income elasticities that extends from 0.3 to more than 2. Viscusi observes a risk income elasticity of about 1. Id. Mrozek, however, believes the right figure is about 0.5. Mrozek, *supra* note 97, at 265.

Calling for an income adjustment does *not* mean that social regulators should value rich people's life more highly than poor people's in practice. The social value of a life does not depend on the income of the person. The point is simply that the decision to use a single life value for all people in society in no way justifies drawing that value exclusively from the low-income segment of society, or from a lower-income time period, with no adjustment to reflect the higher incomes of others, or income growth.

106.   Fatal Tradeoffs, *supra* note 15, at 52 (comparing the income of the average U.S. airline traveler ($32,840 in $1990) with that of workers in labor market study databases ($20,000). See also Value of Risks to Life, *supra* note 94, at 1926-1927 tbl 2, and 1930. Revesz also reports a roughly 33 percent gap between blue-collar workers and median US earnings, and calls for an appropriate value adjustment. See Revesz, *supra* note 21, at 968.

107.   The per capita real income growth figure is derived from US Census Bureau, Statistical Abstract of the United States 422, tbl. 647 (2001). 1982 is the *latest* year of the labor market data used to establish Viscusi's and Hahn's $3-7 million range of life values. See Fatal Tradeoffs, supra note 15, at 53, tbl. 4-1 (Panel Study of Income Dynamics, 1982) EPA's guidelines for its own cost-benefit analyses call for adjusting historic labor market numbers for inflation but not for real income growth. See EPA EA Guidelines, *supra* note 96, at 89, tbl 7-3 (2000).

to grow over the course of any latency period following exposure to a carcinogen.[108] Hahn's 2000 study does not even account for *inflation* after 1990.[109] As Annex E reveals, depending on one's assumptions about the income elasticity of risk value, simply making the required inflation and income adjustments would increase Hahn's $3-7 million life values by a factor ranging from three to five.[110]

6. Hahn's base case employs a discount rate of 5 percent which is well above the "consumption" rate of interest (2-3 percent) that many economists believe is the appropriate rate for discounting future benefits to consumers in an open economy.[111] Correcting this discrepancy would have increased Hahn's baseline life value for cancer risks by an additional 33%.[112]

7. Opposing these downward biases is a possible upward bias in measured life value. The upward bias arises from the fact that social regulations benefit citizens across the board (particularly the elderly, in the case of cancer risks) while labor market studies examine the choices of individuals in the prime of life. Though the propriety of such an adjustment may well be questioned (it implies that older people's lives are worth less than the lives of others), Revesz believes accounting for this difference would reduce the measured life-saving value of social regulation by 40-50

---

108. Revesz exposes the failure of current values to account for real income growth over latency periods. Revesz, *supra* note 21, at 963. But he misses the more serious failure to account for real income growth from the data-year of relevant studies to the present. In a recent comment on another subject, Heinzerling points out, in passing, that the life values derived from old labor market studies have never been adjusted for economic growth. She fails to notice the dependency of such adjustments on contestable assumptions about income elasticity of risk preference. See Lisa Heinzerling, Markets for Arsenic, 90 Geo. L.J. 2311, 2320 (2002).

109. Government's Numbers (2000), *supra* note 13, at 39 (using the same $3-7 million range that Viscusi puts forward in 1992, in 1990 dollars, for benefits expressed in 1995 dollars. Simply accounting for inflation over that five year period would raise the base case live value from $5 million to $6 million. See U.S. Census Bureau, Statistical Abstract of the United States 451 tbl 691, Purchasing Power of the Dollar: 1950 to 2000 (2001).

110. In Annex E, the required adjustment for non-cancer risks is given by the ratio of cell B7 to B4 (2.5x), if income elasticity is 1; or the ratio of cell F7 to F4 (1.9x), if income elasticity is 0.5. The adjustment in respect of cancer risks is B14/B4 (3.8x) if elasticity is 1; and F14/F4 (2.5x) if elasticity is 0.5.

111. Compare Government's Numbers (2000), *supra* note 13, at 39, with Kenneth J. Arrow, Maureen L. Cropper, George C. Eads, Robert W. Hahn, Lester B. Lave, Roger G. Noll, Paul R. Portney, Milton Russell, Richard Schmalensee, V. Kerry Smith, and Robert N. Stavins, Benefit-Cost Analysis in Environmental, Health and Safety Regulation: A Statement of Principles at 13 (1996)[hereinafter Annapolis Principles] ("The rate at which future benefits and costs should be discounted to present values generally will not equal the rate of return on private investment. The discount rate should instead be based on how individuals trade off current for future consumption."); see also Revesz, *supra* note 21, at 979. However, recent research suggests that discount rates are not constant, and that short-term discount rates may be much higher than this, declining asymptotically to a 1-2 percent rate over 20 years.

112. The figure is calculated as $1-1(1+r)^{20}$, where 20 represents the assumed latency period of cancer, in years, and r is the discrepancy between Hahn's discount rate and the proper rate (2 percentage points in this case).

percent, in the case of cancer fatalities that accrue to elderly people after a twenty-year latency period.[113]

What is the net effect of the omitted adjustments on Hahn's assumed life values? As Annex E indicates, the net effect may well be an under-statement of the value of life by a factor of 3.5-5.5. Indeed, this should be regarded as a conservative estimate of the under-valuation, since it fails to reflect needed (but omitted) upward adjustments to account for the greater risk tolerance of high-risk workers and the cumulative nature of the multiple risks addressed by agencies using uniform values.

The discussion so far has focused exclusively on the value of life. Hahn's values for injuries and illnesses are even less defensible. To begin with, he recognizes only two categories of morbidity – injuries/illnesses causing loss of workday, and "other."[114] This is obviously unrealistic. He also assigns these categories arbitrary values – one-hundredth and two-hundredths of a life, respectively – that take no cognizance of the vast range of loss (including pain and suffering) associated with injuries and illnesses short of death. Finally, in under-estimating the value of life, Hahn *ipso facto* under-estimates the value of illnesses linked to the value of life.[115]

One response to the problems of valuation identified above is, obviously, to recommend raising the estimated value of life to reflect the required adjustments. Another, more candid, response, in this author's view, would be simply to conclude that both the primary values and the adjustments are too speculative to warrant much reliance: we simply do not *know* what the income elasticity of risk value is, or how to adjust for involuntary, cumulative, or dread risks. This suggests that policy makers should simply acknowledge frankly that the values they attach to avoiding risks to life and health are policy judgements, for which they and their bosses will (and should) be held accountable in the political marketplace. Either way, the main point for present purposes remains the same: we should be profoundly skeptical of the life and health values employed in Hahn's scorecard. They may be consistent with current agency practice, but they are not supported by economic logic or data, and they are probably far too low.

E. *Discounting lives (Morrall and Tengs/Graham)*

One way to avoid the treacherous terrain of life valuation is by doing as Tengs/Graham and Morrall do: evaluate regulations on the basis of the basis of cost per life saved without trying to assign a monetary value to the lives thus saved. This might have provided an escape from the dilemma of valuation had those authors not immediately thrown themselves back into the

---

113. Revesz, *supra* note 21, at 966. It bears mention, however, that no politician or government official, to this author's knowledge, has yet been willing to assert baldly that the life of a 40-year-old is worth twice that of a 60-year-old, inasmuch as the former has twice the remaining life expectancy of the latter. One wonders why, if economists are really capturing the views of ordinary Americans, no politician is willing to state such views publicly.

114. Government's Numbers (2000), *supra* note 13, at 39.

115. Id.

soup by insisting on discounting the *number* of lives saved in future years.[116]

"Discounting lives" means, in a nutshell, that a regulation which saves 100 lives after a twenty-year latency period is deemed to save only 61 lives at a five percent discount rate, and 37 lives at a seven percent rate. Discounting lives at ten percent for forty years, as Morrall appears to have done, has the effect of reducing the 100 lives saved to only 2, thereby increasing the cost-per-life-saved by a factor of fifty.[117]

What is wrong with discounting 100 lives saved in forty years to 2? There are at least two things wrong with it, both of them fairly obvious. One problem is that death does not recognize human accounting conventions and death does not discount. As a result, if one million people are exposed to a toxic chemical that produces a 1:10,000 probability of fatal cancer among those exposed, then the odds are quite high that 100 people (not 61, 37, or 2) will lose their lives to cancer as a result of the exposure.

Moreover, whatever the interior logic (to economists) of discounting monetary values for risk to life, the average reader of the Tengs/Graham articles or the Morrall table quite understandably does not appreciate that the physical reality of 100 lives saved in twenty years is being presented as 2 lives saved today, or that 42 years of life extension are being shrunk (by the magic of discounting) to 10 or 17 years of life. How many laymen, one wonders, would agree that a miracle drug which allows a 35-year old woman to reach the age of 77 adds only 17 years to her life? Most people would consider that bad math. Yet that is the arithmetic of scorecardists who practice discounting. Whether or not it constitutes sound economics, it is misleading and therefore objectionable, as a matter of English usage.[118]

A far better approach is simply to follow OMB's advice to agencies:

"As a first step, you should consider presenting the streams of benefits and costs over time. These 'raw' streams of benefits and costs can help

---

116.   Opportunity Costs, *supra* note 10, at 169; Morrall, *supra* note 8, at 28.

117.   Heinzerling offers an excellent discussion of the impact of discounting in inflating Morrall's cost-per-life-saved estimates, in Mythic Proportions, *supra* note 15, at n. 8-10, and accompanying text.

118.   Morrall has defended his practice of discounting lives in the following terms: "Discounting costs but not benefits leads to absurd results, such as that a rule saving 100 lives a decade from now is more desirable than a rule of equal cost saving 99 lives right away, and that all rules yielding continuous benefits are worth any amount of immediate costs." Morrall, *supra* note 8, at 28. Both arguments fail. The choice between 100 lives saved a decade from now and 99 lives saved today may seem obvious to Morrall. But, obvious or not, it is fundamentally a moral choice, not an economic one, which can and should be preserved for policy-makers by simply announcing the number and timing of lives saved, free of discounting. Morrall's second argument -- that, without discounting, "all rules yielding continuous benefits are worth any amount of immediate costs" -- is a piece of sophistry which ignores basic precepts of regulatory evaluation. As Morrall knows full well, all regulations yield streams of costs and benefits that are, for analytical purposes, truncated at the end of some stipulated planning period. Hahn, for example, assumes that the rules he studies will be in effect for twenty years, meaning that costs are truncated after twenty years, and benefits are truncated after twenty-years plus whatever the assumed latency period is. Government's Numbers (2000), *supra* note 13, at 40. So trivial benefits do not and cannot, in practice, accumulate to infinity over a period of infinity.

you – and your reader – better understand the effects of alternative regulatory actions."[119]

If only agencies and scorecardists would follow this sound advice, they could avoid much of the confusion caused by discounting lives or values of risk to life.

F.   *Logically unsupported conclusions (Tengs/Graham)*

The Morrall and Hahn studies may use unreliable data and dubious methods, but at least their conclusions follow from their data. The same cannot be said of the Tengs/Graham studies. These studies make three main assertions: (a) irrational regulation kills (the 60,000 lives claim); (b) the existing pattern of regulation is grossly inefficient; and (c) EPA and OSHA toxic-control regulations are the worst of the lot.[120] Yet this section will show that their own data do not establish any of these propositions.

1.   *Tengs/Graham's data do not prove "statistical murder"*

Although the statistical murder charge is sensational and widely repeated, it rests entirely on two counter-factual assumptions. The first is that the United States government operates under a fixed national regulatory budget for allowable compliance cost, so that every private sector dollar spent to reduce Risk A is a dollar taken away from efforts to mitigate Risk B. The second is that there is some mechanism in place for re-allocating to better uses the savings achieved by zeroing out high-cost uses. In fact, there is no such compliance cost budget, and no such re-allocation mechanism.[121]

The reality is that we live in a $9 trillion dollar economy of which only a tiny sliver is spent on regulatory risk reductions. If money spent cleaning

---

119. OMB Guidelines, *supra* note 89, at 6.

120. See, respectively, Opportunity Costs, *supra* note 10, at 172 (claiming that an additional 60,200 lives could be saved by rationally re-allocating resources to high value life-saving interventions); Five-Hundred Interventions, *supra* note 9, at 371, 372 (claiming that "efficiency in promoting survival requires that the marginal dollar spent be the same across all programs" whereas in the authors sample the marginal cost-per-life-saved ranged from less than zero to more than $10 billion per life year saved); Id. at 371(claiming that the median toxic control intervention costs $2.8 million per life-year, compared to $42,000 for the median medical intervention and $48,000 per life-year for the median injury reduction intervention).

121. Nor has Dr. Graham ever proposed establishing such a re-allocation mechanism in his capacity as President Bush's regulatory czar. Regulatory critics *have* proposed creating the regulatory budget that claims of statistical murder assume. See, e.g., Robert W. Hahn, Achieving Real Regulatory Reform, U. Chic. Legal F. 143, 153 (1997) ("Congress should introduce a binding regulatory budget on an experimental basis."); S.L. & D.R., Cost defective, Forbes 200 (Dec. 16, 1996) (reporting introduction of legislation to impose a regulatory budget to limit compliance costs that federal agencies may impose). With such a budget in place, it would then be true that a dollar spent on Risk A is necessarily subtracted from Risk B. Congress and agencies would then be forced into a painful triage, with lives at stake, which might produce more "efficiency." Of course, it also would force agencies either to ignore large, newly discovered risks or cancel programs in place to make room in the risk budget cap. To date, Congress has not seen fit to create a regulatory budget. Undaunted, Graham and others simply assume such a budget exists by crafting a theory of 'statistical murder' into which the assumption is smuggled.

up hazardous waste sites might save more lives if re-directed to combat smoking, then so might a portion of the $36 billion spent each year on lottery sales,[122] the $92 billion spent on alcoholic beverages,[123] the $7.6 billion spent on spectator sports,[124] or the $54 billion spent on tobacco.[125] By the logic of Tengs/Graham, lottery sales "kill" 4,500 people every year, while spectator sports "kill" 950 statistical people.[126] Indeed, by the logic of Graham and Tengs, every highly paid baseball player or corporate CEO is a statistical murderer since, like regulators, they consume resources that might be devoted to risk reduction.[127]

Heinzerling finds an implicit political agenda in Graham's selective focus. As she points out, Tengs and Graham "do not ask, for example, whether the billions of dollars in subsidies to the mining, logging, ranching and farming industries might be better spent on, say, smoking cessation and childhood immunizations. They do not even ask whether money spent subsidizing tobacco itself might be better spent on smoking cessation programs."[128]

Noting its selective focus is not the only way to appreciate the fallacy of Tengs' and Graham's 60,000 lives claim. Another way is simply to examine the actual interventions which, starved of funds in Tengs/Graham baseline scenario, do most of the new life-saving in reallocation. Annex B-1 reveals that just two interventions – continuous (versus nocturnal) oxygen for hypoxemic obstructive lung disease, and influenza vaccines for all citizens – account for over 42,000 of the 60,000 additional lives saved by re-allocation.[129] Yet few would suggest that the nation's failure to provide continuous oxygen for hypoxemic obstructive lung disease is somehow caused by excessive regulation of benzene or other interventions at the "cost-ineffective" bottom of the list.[130] The two sorts of interventions do not

126. These figures assume a $8 million marginal cost of saving a life.

127. Heizerling makes the same point using the examples of soft drinks, fad diets, leaf blowers and Nicoret gum. Five-Hundred Interventions and Their Misuse, *supra* note 19, at 162.

128. Id.

129. See Annex B-1, rows 20 and 22.

130.   See Annex B-1, rows 170-186. Other scholars have postulated a different linkage between regulatory spending and mortality, whereby money spent on low-risk interventions reduces personal income and health care expenditures, thereby increasing mortality overall. See, e.g., Ralph L. Keeney, Mortality Risks Induced by Regulation, 8 J.

compete with each other. Addressing low risks with expensive regulations may be inefficient in some sense, and it may therefore be a waste of money. But it is not killing anyone.

Of course, inefficient regulation may be undesirable, even if it does not kill. The question then arises whether Tengs/Graham at least establish a pattern of inefficient over-regulation of small risks. The next sub-section will show that they do not.

2. *Tengs/Graham do not establish pervasive over-regulation of small risks*

In *Five-Hundred Interventions*, the authors uncover a wide disparity in the median cost of regulatory interventions when measured in cost-per-life saved. From this, they conclude that the existing pattern of regulation is inefficient because "efficiency in promoting survival requires that the marginal benefit per dollar spent be the same across programs."[131]

This statement reflects a fundamental misapprehension of basic economics. Contrary to Tengs/Graham, efficiency does not require that all regulatory "investments" exhibit the same marginal return. There is, for example, nothing inefficient about a portfolio of regulation which includes both "automatic shoulder seat belts in cars (at $94,000 per life-year saved) and "automatic fire extinguishers in airplane lavatory trash receptacles" (at $279,000 per life saved).[132] One cannot, after all, put fire extinguishers in more than all receptacles or install automatic belts in more than all cars. Thus, an efficient portfolio of regulatory investments may (and most likely will) contain programs showing a wide range of cost-per-life-saved. The efficiency criterion does not preclude this. It simply precludes putting low-benefit programs into effect while leaving higher-benefit programs un-implemented.[133]

---

130. (...continued)
Risk & Uncertainty 95 (1994); and W. Kip Viscusi & Richard J. Zeckhauser, The Fatality and Injury Costs of Expenditures, in The Mortality Costs of Regulatory Expenditures: A Special Issue of the Journal of Risk and Uncertainty, 8 J. Risk & Uncertainty 5 (W. Kip Viscusi, ed., 1994). Estimates of the marginal expenditure that would lead to the loss of one statistical life range from $3 million to $70 million. W. Kip Viscusi, Risk-Risk Analysis, 8 J. Risk & Uncertainty 5, 8 tbl.1, and 12 (1994). If we take $8 million per life as the threshold of "efficient" spending, then about $2.6 billion of the $21 billion total spending in the Tengs/Graham database is inefficiently spent. This corresponds to 78 - 867 lives lost due to inefficient expenditures under "income effect" hypotheses – still significant, but a far cry from the 60,000 "statistical murders" alleged by Graham and Tengs. Moreover, even the more attenuated linkage between income-health care spending and mortality is most likely illusory, for reasons set forth *infra* Section II.A.1.g.

131. Id. at 372.

132. See Annex B-1, rows 30 and 43, respectively.

133. The life-saving maximization problem is essentially a constrained optimization problem in which the constraint is that no single intervention can be more than 100 percent implemented. Once the implementation level for any intervention reaches 100 percent, it is necessary to allocate any remaining risk reduction dollars to the next most cost-effective intervention, and so on. The result over many interventions may well be a wide range of costs-per-life-saved even in the optimized allocation. Indeed, Graham and Tengs' Opportunity Costs study contains just such a "rational" re-allocation. As seen in Annex B-1,

A second problem with *Five-Hundred Interventions* has been well documented by Heinzerling: the authors include in their database all sorts of interventions that are not regulatory programs at all, and that, in fact were never implemented or even proposed by any government official.[134] Obviously, one cannot draw conclusions about the efficiency of government regulation from data that fail to distinguish between real and hypothetical programs, or between government programs and private sector actions.

Opportunity Costs stands on firmer ground.[135] It cures the probative shortcomings of the former study by generating, for each intervention, an estimate of the degree of implementation along with published estimates of the full-implementation costs and life-saving.[136] This produces the baseline spending scenario reproduced in Annex B-1: $21.35 billion spent to save 56,700 lives.[137] The authors then use their linear optimization model to calculate that 60,200 additional lives might be saved at the same cost, or $31 billion conserved without additional loss of life, through an optimal re-allocation of compliance spending.[138] The opportunity to save 60,200

---

133. (...continued)
their "efficient" re-allocation of life-saving dollars produces a portfolio of interventions that display costs per life saved ranging from negative $8.5 billion to positive $8 million.

134. Humbugs, *supra* note 31, at 653-655.

135. Heinzerling has criticized the latter study as well for including non-implemented interventions. See Five-Hundred Interventions and Their Misuse, *supra* note 19 at 156; and Humbugs, *supra* note 31, at 663. This criticism misapprehends what Opportunity Costs is trying to do. The idea in that study is to see how many additional lives or dollars could be saved by re-allocating funds from partially or fully-implemented (but cost-ineffective) programs to non-or partially implemented (but cost-effective) interventions. Re-allocation would be impossible if all interventions in the database were required to be fully funded in the baseline. Moreover, un-implemented and exorbitantly expensive interventions do not skew the analysis because they do no work. They are not implemented in the baseline; they remain non-implemented in the re-allocation; they add nothing to the total of lives or money saved by re-allocation. The same is true of highly effective interventions which are fully implemented in both scenarios. The only interventions that matter to the re-allocation exercise are (a) high-cost interventions that are at least partially implemented in the baseline and (b) lower-cost interventions that are not fully implemented in the baseline. All savings in lives and/or cost come from re-allocating compliance expenditures from group (a) to group (b). Nor is there merit to Heinzerling's objection, Id. at 663, that *Opportunity Costs* re-allocates funds among government and non-government interventions (such as hospital practices) without distinction. In practice, virtually all hospital practices (and other life-saving or endangering private sector activities) are potential subjects for government regulation, and hence fair game for regulatory re-allocation exercises.

136. Regrettably, the implementation estimates are unpublished, leaving the general reader with no way to determine which interventions are implemented and which are not, or to verify implementation estimates. See discussion *supra* Section I.A.

137. See Annex B-1, cells G188 and H188.

138. Opportunity Costs, *supra* note 10, at 172. While the authors provided a spreadsheet setting forth their baseline scenario, they did not provide a spreadsheet setting forth their reallocation pattern of spending. This author's attempt to replicate their re-allocation generated a number for total additional life saving (60,906) that is very close to Tengs/Graham's number (60,200), but is not exactly that number. The discrepancy of less than two percent is most likely explained by differences in the way this author and Tengs/Graham defined "clusters" of competing interventions which save lives by alternative

additional lives at no extra charge through re-allocation seems like a telling indictment of our propensity to lavish regulatory compliance dollars on small risks.

Close inspection of the authors' data reveals a rather different picture, however. Annex B-1 reveals that the authors have included in their baseline eleven non-implemented interventions which, when fully implemented in re-allocation, save $9.5 billion more than they cost.[139] By contrast, if we take $8 million per life as the threshold of efficient life-saving expenditure, only about $2.6 billion is spent on "inefficient" life saving interventions.[140] In other words, for the interventions in the Tengs/Graham Opportunity Costs database, nearly four times more money is wasted by failing to regulate than is lost by over-regulating.[141]

Moreover, the Opportunity Costs study is hardly a robust demonstration of systemic over- *or* under-regulation. As seen, two-thirds of the 60,000 additional lives saved through re-allocation in that study are associated with just two interventions.[142] Nearly 95 percent of the 60,000 additional lives are saved by fully implementing just nine interventions, of which three are medical, five are traffic-related and one is environmental.

On the expenditure side, Table 2 of Annex B-2 reveals that optimization results in the re-allocation of about $17.7 billion, of which *ninety percent* is generated by just eight interventions. Indeed, over half of the $17.7 billion is supplied by the opinion of a single author that it would be much more

---

138. (...continued)
means in identical situations. Obviously, only one intervention in each cluster can be fully implemented in re-allocation. The other interventions must be zeroed out – otherwise, life saving from re-allocation will be double or triple counted. Unfortunately, the authors' spreadsheet is not always clear as to which interventions are being grouped together in clusters. The slight discrepancy between this author's and Tengs/Graham's estimates of additional life-saving from re-allocation most likely derives from this author's use of slightly different definitions of competing clusters.

139. See Annex B-1, rows 3-13 of column C and cell G197. The number in cell G197 is derived by subtracting the sum of cells G3 through G13 (total baseline spending on negative-cost interventions) from the sum of cells I3 through I13 (total re-allocation spending on negative-cost interventions). This is the amount released for life-saving elsewhere by fully implementing negative-cost interventions in the reallocation scenario.

140. Annex B-1, cell G193. For a defense of the $8 million threshold see discussion *supra* I.D. The $2.6 billion figure is derived by summing the baseline cost of all interventions which display a marginal cost per life (Column D) of more than $8 million. These interventions are listed in rows 104 through 187. $2.6 billion represents the sum of baseline spending (Column G) on these interventions. It should be noted, however, that the total spending on "inefficient" interventions is highly sensitive to the stipulated threshold of efficiency. At a threshold of $7 million per life, $17 billion (almost 80% of total baseline spending) is "inefficiently" spent. See Annex B-1, row 194. The lack of robustness is due to the fact that one intervention – South Coast of California ozone control – accounts for *$15 billion* in baseline spending at an estimated cost of $7.5 million per life saved. See Annex B-1, row 101.

141. See also Annex B-1, rows 103-186.

142. See supra note 109 and accompanying text. See also Table 1 of Annex B-2.

cost-effective to ban residential growth in tsunami-prone areas than to construct sea walls to control the damage.[143]

These few interventions do yield startling numbers. While few will be amazed by news that many more lives might be saved on the road, the possibility of saving 42,000 additional lives a year with just two medical measures is, if true, surprising, to say the least. One wonders why this was not the headline of their article. In fact, the authors do not even mention these amazing life-saving opportunities in their published report. Nor has John Graham, an author of the study and the current regulatory "czar" of the Bush administration, done anything in office to further the cause of oxygen for hypoxemics, to advocate flu vaccines for all, or to promote a ban on residential growth in tsunami-prone areas. One wonders whether he believes his own data, or if he is even aware of them.

The major point for present purposes, however, is that the *Opportunity Costs* results are not robust: they are dominated by a handful of interventions that certain authors believe should, or should not, have happened. They do not establish a pervasive pattern of gross over-regulation of small risks. Indeed, if they reveal any pattern at all, it is one of significant under-regulation, with no evidence that over-control is somehow causing under-regulation.

If the Tengs/Graham data fail to prove systemic over-reaction to small risks, we are left with the final question of whether *Opportunity Costs* at least establishes that toxics regulations are singularly prone to inefficient over-regulation.

3. *Tengs/Graham's data do not prove that toxics-related regulations are particularly inefficient*

Annex B-3a contains the authors' spreadsheet numbers for all non-toxic-related interventions. Annex B-3b contains the authors' spreadsheet numbers for the toxic control interventions in their sample. If we again take $8 million per life as our provisional threshold of efficiency, these annexes indicate that about *four percent* of the funds spent on toxic-exposure-related interventions were spent inefficiently in the baseline case, whereas sixty-three percent of the non-toxic related interventions were spent inefficiently. In other words, the authors' own data suggest that toxic control programs are fifteen times more efficient than their non-toxic counterparts in their overall pattern of spending to save lives.

How do we reconcile the relative efficiency of spending on toxin control with the author's findings in Five-Hundred Interventions that toxic control interventions exhibit median costs per life saved orders of magnitude higher than interventions in other areas?[144] The answer is straightforward. As Annex B-3b reveals, most of the high-cost interventions for toxics in the sample are either not implemented, or implemented at low compliance-cost

---

143. See Annex B-2, Table 2, rows 3 and 139. The source for these data is given in Five-Hundred Interventions, *supra* note 9, at 389.

144. Five-Hundred Interventions, *supra* note 9, at 371 ("the median medical intervention costs $19,000/life-year (n=310); the median injury reduction intervention costs $48,000/life-year (n=133) and the median toxin control intervention costs $2,800,000/life-year (n=144)."

levels. Non-toxic-related interventions, on the other hand, are much more likely to be implemented notwithstanding an inordinately high cost.

****

This Part has shown that the Morrall, Hahn, and Tengs/Graham scorecards contain a range of methodological errors: concealed data, arbitrary and non-transparent calculations, non-replicable conclusions, selection bias, confusion of *ex ante* guesses with ex post measurements, and systematic under-valuation of life and health benefits, and/or inferences unsupported by data. These errors – which might have been avoided through more careful analysis or reporting – are sufficient in themselves to undermine these scorecards as a basis for claims about government regulation.

The next part takes up a group of equally serious and additional errors which could not have been avoided, because committing these errors is at the very heart of the scorecard enterprise. Scorecards could not be scorecards if they did not commit the errors about to be discussed.

II. CRITIQUE OF THE TESTS: GENERIC DEFECTS

Besides the avoidable errors discussed in the preceding part, the Hahn, Morrall, and Tengs/Graham scorecards also exhibit a number of analytical defects which appear to be endemic to the scorecard enterprise. This Part discusses three such shortcomings: (A) the disregard of whole categories of unquantified costs and benefits (and, amazingly, many benefits that agencies quantified); (B) disregard of distributive impacts; and (C) failure to disclose the true level of uncertainty in the analysis.

A. *Disregarding unquantified (and some quantified) costs and benefits*

Perusing Hahn's unpublished spreadsheet of regulatory costs and benefits (reproduced in Annex C) yields a startling discovery. Forty-one of the 136 rules in his database -- fully thirty percent of all the rules – are assigned a zero benefit. These rules, it should be emphasized, are not rules for which it is claimed that costs equal benefits. These are rules alleged to offer no benefit whatsoever.

The list of zero benefit rules includes:

– a rule requiring that owners and operators of oil tankers develop plans to respond to large oil spills (row 28);

– a rule requiring double hull construction for oil tankers like the Exxon Valdez (row 29);

– a rule to implement 1990 Clean Air Act Amendments which require that certain sources of air pollutants hold permits and comply with permit conditions (row 51);

– a rule requiring the public reporting of releases of certain toxic chemicals from manufacturing facilities (row 67);

– a Clean Water Act rule aimed at protecting sensitive coastal areas from non-point-source water pollution (row 73);

– a Clean Water Act rule establishing technology-based water pollution discharge standards for electroplating and metal finishing point sources (row 76);

– a rule to protect agricultural workers from exposure to harmful pesticides (row 78);

– a rule establishing financial responsibility requirements for owners and operators of underground storage tanks (row 88)

– three rules establishing national primary drinking water standards to limit public exposure to toxic pollutants in drinking water (rows 91, 94, and 95, respectively);

– a regulation banning the manufacture and sale of products containing PCBs, a highly toxic and bioaccumulative substance (row 98);

– an HHS rule requiring improvements in clinical laboratory practices (row 102); and

– an FDA rule establishing requirements for the safe handling of seafood in commercial processing operations (row 100);

– a proposed rule to prevent or reduce oil spills from non-transportation-related on-shore oil handling facilities (row 127).[145]

It turns out that Hahn, with a few narrow and limited exceptions, has assigned a zero value to any benefit which the government's regulatory impact assessment does not quantify and monetize.[146] Hahn also zero-values benefits that are quantified and monetized in an agency RIA, unless they happen to fall into one of his select categories of recognized benefit – even as he insists that he is using the government's numbers.[147]

Nor are the omissions of unquantified variables confined to zero-benefit rules. Rules that display a positive number in the benefits column turn out, on closer inspection, to have had whole categories of important benefits

---

145. The zero benefit entries listed above are represented by a '-' in column 8 of each indicated row in Annex C.

146. All unquantified benefits are assigned a zero value. As seen in more detail below, Hahn will monetize the value of a benefit which the agency has quantified but not monetized in the case of benefits involving (1) avoidance of cancer, heart disease or lead poisoning, (2) avoiding of accidental death or injury; and (3) pollution from any of four named air pollutants.

147. The exceptions (which Hahn monetizes regardless of whether the agency does so) are health benefits of reducing emissions of a small group of air pollutants -- carbon monoxide, hydrocarbons, nitrogen oxides, particulate matter and sulfur dioxide – on a per-ton-of-reduction basis. These benefits are counted only if the agency has quantified the lives saved, illnesses or injuries averted, or tons of a certain air pollutant removed. All other benefits are zero-valued. Government's Numbers (2000), *supra* note 13, at 40.

excluded from the tally.[148] The result is forty-one zero-benefit rules and an indeterminate number of other rules for which whole categories of benefits have been summarily excluded.

Morrall and Tengs/Graham adopt an even more extreme accounting convention: by evaluating every regulation solely in terms of cost-per-life-saved, they manage to exclude non-life-saving benefits entirely.

These scorecards also omit certain unquantified costs: costs of record keeping and enforcement, diversion of management time, lost productivity, diminished competitiveness (though most studies find competitiveness effects of most regulations are small), and so forth.[149] Agencies pay scant heed to these costs and scorecards neglect them altogether. Yet they clearly exist.

Perhaps the best way to appreciate the nature and consequence of cost and benefit omissions is to examine a sample of the actual cases in which they occur. Sub-section (1) documents the nature and consequence of these omissions for the analysis of particular regulations. Sub-section (2) shows that the categorical exclusion of unquantified variables is both endemic to scorecards and inconsistent with basic principles of cost-benefit analysis.

1.   *A taxonomy of excluded costs and benefits*

This author's audit of the rules in Hahn's database reveals seven common situations in which benefits and/or costs are likely to have been omitted: (a) quantified and/or monetized benefits that the scorecard does not recognize; (b) procedural benefits; (c) interlocking benefits; (d) benefits that are hard to measure; (e) statutorily mandated benefits; (f) indirect costs; and (g) costs associated with risk-risk tradeoffs. Examination of these rules suggests (though it does not prove) that the omissions are most significant on the benefit side of the ledger.

a.   *Quantified but unrecognized benefits*

Morrall and Tengs/Graham exclude all benefits other than human life-saving, regardless of whether an agency has quantified and/or monetized them. Hahn likewise excludes benefits which agencies have quantified and monetized, but which do not fit into one of his arbitrary categories – even as he insists that he is using the "government's numbers."[150] A few examples drawn from rules in Hahn's database may serve to illustrate the nature and consequence of such exclusions.

Agricultural Worker Protection. In 1992 EPA promulgated an agricultural worker protection standard for pesticides. Noting that the rule would help protect 3.9 million agricultural workers across the United States who are exposed to pesticides in their work, EPA predicted the following benefit:

---

148. See, e.g., Great Lakes Water Quality Guidance, discussed *infra* at note 202 and accompanying text.

149. See discussion *infra* Section II.A.1.f.

150.   See Morall, *supra* note 8 at 30; Opportunity Costs, *supra* note 10; and Government's Numbers (2000), *supra* note 15, *passim*.

"avoiding 8,000-16,000 physician-diagnosed (non-hospitalized) acute and allergic pesticide poisoning incidents, [while] avoiding about 300 hospitalized acute and allergic pesticide poisoning incidents, and avoiding potentially important numbers of cancer cases, serious developmental defects, stillbirths, persistent neurotoxic effects and non-diagnosed acute and allergic poisoning incidents."[151]

Hahn's scorecard, however, does not recognize any "health benefit" other than "reducing the risk of cancer, heart disease, and lead poisoning."[152] Since avoiding stillbirths, persistent neurotoxic effects and pesticide poisoning does not fit within any of these categories, the regulation is assigned a zero benefit. Protecting 3.9 million workers from acute pesticide poisoning thus fails Hahn's cost-benefit test.[153]

Seafood Safety. In 1995, the Food and Drug Administration adopted a final regulation – the "Seafood HAACP [Hazard Analysis Critical Control Point] rule" – to ensure the safe and sanitary processing of fish and fishery products.[154] The rule was strongly supported by the seafood trade association, which informed FDA:

"[The association] strongly supports the adoption of a comprehensive regulatory program by the FDA . . . using HACCP principles. HACCP systems have been applied successfully by individual firms in our industry, and they have been shown to be a very cost-effective way of controlling safety hazards."[155]

The agency's preamble to the regulation notes:

"foodborne illnesses tend to be significantly under-reported to health authorities. Consequently, precise data on the numbers and causes of foodborne illness in this country do not exist. FDA does know, however, that illness from seafood does occur and that a wide variety of hazards have been identified that could cause illness from seafood."[156]

Listed examples include ciguatera poisoning, hepatitis A, Norwalk virus, Vibrio vulnificus (a disease derived from eating an organism of the same name that inhabits raw molluscan shellfish in the Gulf of Mexico), salmonella, paralytic shellfish poisoning, scombrotoxin, and nine other

156.   Id at 65103.

foodborne diseases.[157] FDA estimated that its seafood safety rule would avert from 20,000 to 60,000 foodborne illnesses a year, which the agency valued at $45 to $116 million per year, with additional benefits expected in the form of (1) $20 million in annual cost savings by exporting firms who no longer would need to pay fees for EU inspection services; (2) additional cost savings (unquantified) that would result from there being fewer recalls and fewer enforcement actions and (3) revenue gains (unquantified) from increased consumer confidence in U.S. seafood at home and in export markets.[158] The rule was expected to cost about $60 million in the first year, and about $40 million in subsequent years.[159] FDA therefore found "that the estimated benefits exceed the estimated costs."[160] Hahn, however, counts avoiding seafood illness as a "zero benefit" since it does not involve cancer, heart disease or lead poisoning. That is how the FDA's seafood safety rule – which virtually everyone supported – managed to acquire a zero benefit, and to fail Robert Hahn's "neutral economist's cost-benefit test."[161]

Prevention of Oil Spills. In 1992, the Coast Guard estimated that its oil tanker double hull requirement would yield benefits ranging from $1.1 to $6 billion in avoided oil spills over the transition period 1990-2015.[162] But because Hahn's system counts only certain kinds of benefit – avoiding cancer, heart disease, lead poisoning, injuries from accidents and environmental pollution by one of four air pollutants – the benefit of avoiding major oil spills is valued at zero, even though the government's number is in excess of a billion dollars.[163]

Formaldehyde Exposures in the Workplace. Zeroing out unquantified benefits is not unique to Hahn. Morrall practices it, too, with consequences that can best be illustrated by examining the rule at the bottom of Morrall's table: OSHA's proposed formaldehyde exposure rule which, according to

161. See Annex C row 100.

162. Double Hull Standards For Vessels Carrying Oil in Bulk: Interim Final Rule, 57 Fed. Reg. 36,222, 36,232 (1995).

163. See Annex C, row 29. In this particular case, zeroing out an important benefit did not change the result, since the Coast Guard's RIA predicted that the statutorily-mandated rule would impose costs in excess of the expected monetized benefit. See 57 Fed. Reg. at 36,232 *supra* (predicting that the rule will raise transport costs by about half a penny per gallon, but that, based on historic accident and loss rates and clean-up costs, the rule will cost more than $24,000 per barrel of oil spill averted, producing a net discounted *cost* of $2.1 billion over the period 1990-2015, and over $1 billion per year thereafter). The point made by this example is not that all rules pass cost-benefit analysis, but that Hahn's scorecard does not count all the benefits.

Morrall, would cost an incredible $72 *billion* per life saved.[164] Granted the rule was never finalized. How could any rational agency even propose such a preposterously expensive rule? The answer is found in a combination of Morrall's questionable accounting and the agency's concern with unquantifiable risks.

The rule in question involved a proposal to reduce the Permissible Exposure Level (PEL) for formaldehyde in the workplace from 3 parts per million (ppm) to either 1.0 or 1.5 ppm.[165] OSHA anticipated that employers would meet this goal primarily by installing ventilators in work areas where formaldehyde is present in high concentrations. In addition to these "engineering" precautions, employers would be asked to better monitor exposures and conduct exposure risk and reduction training programs for employees.

The rule would apply principally to manufacturers in five different manufacturing industry categories – hardwood veneer and plywood, particleboard and medium density fiberboard, furniture and fixtures, synthetic resins, and ferrous and nonferrous foundries. [166] OSHA predicted that compliance with the 1.5 PPM PEL would cost these industries about $22.5 million per year, while compliance with the 1.0 PPM would cost $36 million per year.[167] Unfortunately, OSHA does not provide the perspective of total revenues for the affected industries, which makes it difficult to get a clear idea an idea of how burdensome such costs might be. But rough calculations based on Census data for the value of aggregate shipments by producers in the industrial categories named in the OSHA rule suggest that total revenues for these industries in 1985 was probably in the neighborhood of $30 billion.[168] So the estimated cost of OSHA's proposed formaldehyde

---

164.   Morrall, *supra* note 8, at 30.

165.   Occupational Exposure to Formaldehyde: Proposed rule and notice of hearing, 50 Fed. Reg. 50,412 (1985). Respirators (which are uncomfortable and therefore are prone to misuse or non-use) would be prescribed only as a last resort for use in cases where ventilators are shown to be infeasible or ineffective. Id. at 50,464.

166.   SIC codes for these industries are 2435 (hardwood veneer and plywood); 2493 (particleboard), 2499 (fiberboard); SIC 2821 (plastics, resins, and elastomers); and 332/336 (ferrous and nonferrous foundries). Id. at 50,463.

167.   Id at 50,464. All figures are in 1985 dollars. OSHA's exact figures are $38.9 million capital cost and $17 million annual operating cost (1.5 PPM standard) and $57.8 million capital cost and $28.3 million operating cost (1.0 PPM standard). Figures cited in the text above were derived by annualizing capital costs at 7 percent over 10 years and adding these annualized capital cost to the annual operating cost. My annualization of capital cost used the standard formula: annualized cost (AC) = Capital Cost x r x $(1+r)^n/((1+r)^n-1)$, where r is the annualization rate, and n is the period of annualization.

168.   Source: Bureau of the Census, 1994 Annual Survey of Manufactures: Value of Product Shipments, available online at http://www.census.gov/prod/www/abs/value.html. Total revenues cited in text are obtained by adding the 1992 value of product shipments cited in the table for each of the industry and product class codes cited in note 169 *supra*, and then converting that value to $1985 dollars to adjust for inflation during the intervening period, using the consumer price index. This yields an accurate value for 1992 shipments of these product categories measured in 1985 dollars. The relevant statistic, however, is the value of shipments for these products in 1985 when the rule was issued, and that value is not readily available. However, an approximate value for 1985 shipments can be obtained by

(continued...)

exposure protection rule comes out to about *one-tenth of one percent of revenues.*

On the benefit side, OSHA predicted that the 1.5 PPM standard would avert anywhere from 5-42 fatal cancers over a career of exposure, while the 1.0 PPM standard would avoid 6-52 fatal cancers. But OSHA's proposed rule preamble also devotes many pages to the clinical evidence of the non-cancer benefits of a lower standard: reducing or avoiding burning eyes or noses, sore or burning throats, asthma attacks, chronic bronchitis, allergic reactions, dermatitis and skin sensitization. OSHA noted that over 500,000 American workers are regularly exposed to formaldehyde at concentrations that have been found to cause one or more of these illnesses or discomforts.

Is avoiding such discomforts and health hazards for 500,000 American workers – as well as 6-52 lifetime cancers – "worth" the expenditure of seven-tenths of one percent of revenues for a $30 billion dollar group of industries? Will installing ventilators in the workplace also reduce employee exposure to other irritating and possibly hazardous chemical vapors besides formaldehyde? These are the central questions of the formaldehyde rulemaking. They are quite unlike (they are far more nuanced than) the question implicitly posed by the Morrall table: how could OSHA be so stupid as to propose a rule that will cost $72 billion for every life saved?[169]

The preceding examples could be multiplied. They illustrate a central problem with scorecards. Scorecards exclude whole categories of benefit, thereby producing (in many cases) little more than cartoon caricatures of the rules they purport to analyze.

b. *Procedural benefits*

Procedural rules pose particular problems for scorecards because they do not directly save lives or avoid illness or confer environmental benefits. They merely support other policies that do. Yet scorecards treat all such

---

168. (...continued)
deflating 1992 constant dollar shipments by 2 percent per year (the average rate of real income growth) over the seven-year period, 1985-1992. That adjustment yields the value cited in the text above. Of course, these are aggregate revenues for entire industry categories which may be over-inclusive. Also, some producers and industries might be more severely affected than others in these categories, so it nearly certain that some producers would experience cost somewhat higher than seven-tenths of one percent of revenues.

169. Where does Morrall's $72 billion figure come from in any case? Apparently, Morrall began by assuming that the rule would save only 6 cancer deaths (the low end of the agency range) over a 40-year career with an assumed 40-year latency period. Nowhere does Morrall provide a medical justification for assuming a forty-year latency period for cancer. Dividing 6 by 40 yields 0.15 lives saved per year. Discounting 0.15 at 10 percent for the 40 year latency period yields 0.01 discounted lives saved per year, which is the figure that appears in the "Annual Lives Saved" column in the Morrall table. Morrall, *supra* note 8, at 30. But dividing the annual cost of $36 million by 0.01 yields a cost-per-life of "only" $3.6 billion per life. To arrive at his $72 billion cost-per-life, Morrall must have arbitrarily multiplied the agency's cost figure by a factor of 20.

Suppose, now, one uses the agency's cost figures, takes the mid-point of the agency's cancer benefit range (29 lives), assumes a more realistic latency period of 20 years, and do not discount the number of lives saved, for reasons discussed *supra* Section I.E. The cost-per-life-saved under this scenario is $61.7 million – still a high number, but a far cry from $72 billion.

rules as having zero benefit, with consequences that can best be appreciated by considering a few examples.

Toxic Chemical Release Reporting. In 1988 EPA issued a final rule implementing a statutory requirement calling for the public reporting of significant releases of toxic chemicals from large manufacturing facilities.[170] The final rule (issued in the last year of the Reagan Administration) is silent as to the anticipated benefits of this statutory mandate. Scholars, however, have noted that reported releases of toxic chemicals declined dramatically -- from 7 billion pounds in 1989 to 2.5 billion in 1997 -- in the aftermath of the reporting requirement.[171] Hahn assigns the rule a zero benefit.[172]

Operating Permits for Air Polluters. In 1992, EPA issued a rule (mandated by the 1990 Clean Air Act Amendments) that required covered sources to hold operating permits that set out in a single document what each source's air pollution control obligations are. The rule also required that such sources of air pollution pay a fee to support state monitoring and enforcement efforts.[173] EPA described the benefits of the rule in the following terms:

> The title V permit program will enable the source, States, EPA, and the public to understand better the requirements to which the source is subject, and whether the source is meeting those requirements. Increased source accountability and better enforcement should result. . . .[Also] an important benefit is that the permit program . . . will ensure that States have resources necessary to develop and administer the program effectively [by requiring sources to pay the cost of the program]. . . . Greater compliance may result in an improvement in air quality.

But such benefits cannot be reduced to numbers, so the rule is assigned a zero value in Hahn's benefit column, thereby chalking up another (artificial) regulatory failure.

Such, indeed, is the fate of all procedural rules in Hahn's database, including: an EPA rule expressing a preference for treatment over containment in Superfund cleanups; an EPA rule calling for states to develop programs for coastal non-point source pollution control; two EPA rules establishing criteria and procedures for determining conformity of state and federal transportation plans with Clean Air Act requirements; a follow-on EPA rule adding certain chemicals to the Toxic Release Inventory; an EPA rule imposing financial responsibility requirements for owner/operators of

172. See Annex C, row 67.

173. See Operating Permits Regulations of Title V of the Clean Air Act, 57 Fed. Reg. 32,250 (1992).

Underground [oil] Storage Tanks; an EPA rule establishing procedures for the pre-manufacture notification, review and possible testing of toxic substances entering the stream of commerce; and an HHS rule calling for certain improvements in clinical laboratory practices.[174]

While the benefits of procedural rules may be impossible to quantify, it surely is misleading to value such benefits at zero, and even more misleading to claim that in doing so one is simply using the "government's numbers." When Hahn assigns a zero value in the benefit column of the Clean Air Act permits rule, that zero is not an EPA number. That is Hahn's number.

c.   *Interlocking benefits*

Sometimes it is hard to disentangle the consequences of inter-related rules. In such situations, agencies may assign the benefits of one rule to another – never thinking, of course, that the result will be another "failure" in some scorecard. This circumstance is well illustrated by EPA's effort to control coliform contamination of drinking water.

Regulating E Coli contamination of drinking water. In 1989, EPA promulgated a rule establishing a maximum contaminant level of zero for total coliform in drinking water and calling on public water systems to enhance their monitoring and testing of drinking water for coliform.[175] In explaining its decision, EPA observed:

> "The remedial measures necessary to comply with the total coliform rule will also fulfill some or all of the surface water treatment requirements or the forthcoming groundwater disinfection requirements. As with costs, for accounting purposes, EPA is attributing all health benefits resulting from compliance with this rule to the surface water treatment requirements and the disinfection rule for groundwater systems, rather than the total coliform rule, because the interrelationships among them make it impossible to clearly distinguish which benefits are attributable to each rule."[176]

Hahn responds by assigning the rule a zero value and non-zero cost, thereby chalking up another yet another regulatory failures.[177] But the failure in this case – as in many other cases – lies in the accounting, not the regulation.

d.   *Benefits which are hard to quantify or monetize*

Of all the risks that regulations address, the risks of accidents are the easiest to quantify because the chain of causality is clear. Cancer risks, are well understood in some cases (e.g. tobacco) but remain unclear in many

177.   See Annex C, row 95.

others.[178]   Non-cancer health risks are murkier still: non-cancer risk assessment is widely understood to be still in its infancy.[179]   Ecological risk assessment is the most difficult of all: eco-systems are too diverse and complex to permit any but the most rudimentary ecological risk assessments in most cases.[180]

A similar hierarchy of data and knowledge can be found in the area of benefits valuation. The implicit value assigned in the marketplace to the avoidance of occupational risks of accidents can be monetized reasonably well through labor market studies of wage premia paid in accident- prone industries.[181] Involuntary accident risks are harder to value, however. Cancer and non-cancer illnesses are harder, still, due to their diversity, latency, and lack of clear and direct causal link between exposure and consequence.[182] Ecological amenities are virtually impossible to value fully and reliably. Theorists have developed a host of different approaches, but none, as yet, commands a consensus.[183]

---

178.   EPA's landmark report on comparative risk, Unfinished Business, *supra* note 74, reports the results of a large-scale comparative risk assessment organized into four groups to compile comparative risk information about four kinds of risk: cancer, non-cancer, ecological and welfare effects. The authors note that "the cancer work group faced an easier task in comparing risks . . . than did the other work groups [because] [a] basic method for assessment of carcinogenic risk has been adopted by the Agency." See also id., at 24-25 (noting the massive uncertainties that remain in cancer risk assessment, nonetheless).

179.   Id. at 35-41. See also Unfinished Business, App. 2, Report of the Non-cancer Work Group at 1-1 to 1-2 (noting that "There are thousands of different chemicals in the environment that may cause adverse human health effects . . . EPA has had great difficulty in analyzing non-cancer health effects . . . Most program offices do not actually assess risks from non-carcinogens. . . . They merely evaluate the extent to which a regulatory option prevents exposures above the RfD [reference dose or acceptable daily intake] without an explicit calculation of risk.")

180.   Unfinished Business, *supra* note74, at 43 (noting that "No generally applicable methodology for evaluating economic risk currently exists"). See also Unfinished Business, App. III, Report of the Ecological Risk Group at 5 (noting that due to massive data gaps and conceptual uncertainties ecological risk assessment "only rarely is quantitative and almost never probabilistic.")

181.   See Fatal Tradeoffs, *supra* note 15, at 34-74. As seen *supra* Section I.D, however, even these studies produce a rather wide range of implicit life values.

182.   See Five-Hundred Interventions and Their Misuse, *supra* note 19, at 163 (noting that often "life-saving benefits, other than the prevention of cancer, are ignored because cancer prevention is often the only life-saving benefit that can be quantified.") Indeed, neither EPA nor Viscusi have been able to identify a single labor market study that implicitly values cancer risks specifically. See Fatal Tradeoffs, *supra* note 15, and EPA EA Guidelines, *supra* note 96, at 76, 89 (listing studies and noting that "hedonic wage studies tend to focus on accidental deaths occurring among prime aged males while deaths associated with environmental risk often occur among the elderly and may involve an extended latency period. Furthermore, elevated risks in hedonic wage studies are voluntarily accepted while environmental risks are involuntarily borne").

183.   EPA's Guidelines for Preparing Economic Analysis noted in 2000 that "[a]lthough the economics literature is replete with benefit studies, the coverage is patchy considering the broad range of services and stressors addressed by EPA. Especially rare in the literature are examples of wide-scale changes, very small changes, or the consequences of long-term ecological and economic change." EPA EA Guidelines, *supra* note 96, at 98.
(continued...)

When scientific and economic uncertainties combine in a regulatory setting the agency finds itself in a dilemma. If it tries to assign a number to the benefit the number may be attacked as inadequately supported. If the agency assigns a partial number – representing the portion of the benefit the agency is able to quantify more or less rigorously – the number for that portion may be taken as the number for the whole benefit. And if the agency does not assign a number, then it risks having the benefit overlooked altogether.

The dilemma can best be appreciated by looking more closely at a few examples drawn from the scorecards. It will be seen that scorecards systematically zero out whole categories of unquantifiable benefits. It will also be observed, however, that agencies aggravate the problem by frequently inadequate and, indeed, perfunctory treatment of benefits in their own analysis.

The municipal waste combustor rule. In 1995 EPA issued emissions guidelines for existing municipal waste incinerators and new source performance standards for new combustors.[184] EPA predicted the following incremental benefits from the rule:

Table 1

Predicted Emissions Reduction Benefits of Proposed Emissions Guidelines (Existing Sources) and Standards (New Sources)[185]		
Pollutant	New Source Standards	Existing Source Guidelines
Particulate Matter	34%	50%
Acid Gases (Sulfur Dioxide and Hydrogen Chloride)	58%	87%
Nitrogen Oxides	1%	30%
Dioxins	33%	99%
Cadmium	53%	70-80%

183. (...continued)
The most eloquent statement of the Guidelines on this point is implicit and inadvertent. EPA devotes a total of three pages in a two hundred page analysis to ecological benefit valuation. These three pages do not actually offer guidelines. They offer only a brief summary of five different approaches to ecological benefits valuation, without endorsing *any* of them as valid. Id. at 99-99.

184. Standards of Performance for New Stationary Sources and Emission Guidelines for Existing Sources: Municipal Waste Combustors: Final Rule, 60 Fed. Reg. 65,387 (1995).

185. Emissions Guidelines: Municipal Waste Combustors: Proposed guidelines and notice of public hearing, 59 Fed. Reg. 48,228, 48,238 (1994) (existing combustors); and Standards of Performance for New Stationary Sources: Municipal Waste Combustors: Proposed rule and notice of public hearing, 59 Fed. Reg. 48,198, 48,207 (1994) (new combustors).

| Mercury | 72% | 70-80% |
| Lead | 81% | 70-80% |

EPA's estimates for particulate matter, acid gases and nitrogen oxides were translated into emissions tonnage reductions for which Hahn's scorecard supplied a monetary benefit value.[186]   However, one of the primary objectives of the rule was to achieve greater controls on the highly toxic and bioaccumulative heavy metals (cadmium, mercury, lead) and dioxin which hitherto had not been regulated.[187] As EPA noted in the preamble to the final rule:

> "the absence of sufficient exposure-response and valuation information precludes a comprehensive benefits analysis for many of the MWC pollutants. . . . The total benefits would be higher if benefits from reductions of other pollutants were valuated [sic]."[188]

EPA's (unpublished) economic impact analysis warns that because some benefits are unquantifiable based on available data, "applying the benefit-cost methodology to evaluating the regulatory alternatives examined in this analysis is limited to comparing some of the benefits with most of the costs."[189]

EPA's concern was prescient: Hahn's scorecard picks up the value of reducing the ancillary pollutants – particulate matter, nitrogen oxides and sulfur dioxide – while zeroing out all of the benefits which had provided the primary impetus for the rule.[190] However, EPA shares a measure of blame for the omission. While EPA devotes several pages to documenting the toxicity of heavy metals and dioxins in the abstract, nowhere (not even in the two hundred page Economic Impact Assessment buried in its docket room) does EPA address the fundamental, priority-setting questions facing risk managers in that rule: (1) Are current levels of emissions of heavy metal and dioxin creating a significant human health or ecosystem risk? (2) What portion of total emissions, and total risk from emissions, is accounted for by hazardous waste combustors?

While it may be unfair (given data limitations) to ask for numbers in response to these questions, surely courts, policy-makers and the public are entitled to some explanation of why it is that agency risk managers deem emissions from waste combustors a significant risk. We are left with a record that fails fully to prove the rationality of the rule. But that certainly does not justify Hahn's assertion (as manifest in his negative net benefit number) that the rule is demonstrably irrational.

Great Lakes Water Quality Guidance. An excellent illustration of both the risk characterization dilemma and the way agencies aggravate it may be found in the Great Lakes Water Quality Guidance. In 1995, EPA promulgated guidelines for the Great Lakes states aimed particularly at controlling persistent pollutants such as mercury, cadmium, lead, PCBs, DDT, dioxin, chlordane, heptachlor, dieldrin, pentachlorobenzene, and mirex.[191] These persistent pollutants "bio-accumulate" in the food chain and are toxic at very low levels of chronic exposure. So EPA established ambient limits for concentrations of these and similar pollutants in the Great Lakes and their feedwaters, and instructed the bordering states to develop implementation strategies to achieve these limits.[192]

On the cost side, EPA estimated that the incremental costs of complying with these measures might range from $60 to $240 million ($1994), with the low end of the range being more likely in light of the flexibility and discretion left to states.[193] But how does one go about monetizing all the life-saving, health-enhancing, recreational and non-use values that are enhanced by reducing the discharge of persistent, bio-accumulative toxins into the Great Lakes?

EPA ultimately concluded that available data permitted reliable quantification only of the benefits of reduced incidence of fatal cancer to sports anglers and Native American subsistence fishermen who eat fish that they themselves have caught in the Great Lakes. So the agency assigned a number to this very narrow and partial benefit. That number, after extensive manipulation, became Hahn's number – $12 million – for the *total* benefit of the rule spread over 20 years.[194] All other benefits of eliminating the yearly discharge of 6-8 million toxic-equivalent pounds of pollutants into the Great Lakes were assigned a value of zero.[195]

Not until 1999, when EPA re-visited the rule, would the rulemaking record make clear what had been overlooked five years earlier. In that year EPA proposed a follow-on rule to prohibit the use of "mixing zones" (i.e. dilution areas) in calculating water-quality based effluent limits for discharges of persistent pollutants into the Great Lakes and their feedwaters. The idea was to limit the ability of dischargers to simply dilute discharges as opposed to cleaning up the effluent before discharge. This time, EPA went to some lengths to describe in words (if not numbers) the benefits of reducing bioaccumulative toxic loading in the Great Lakes: reducing human risks of cancer, neurotoxicity, fetotoxicity, endocrine effects, hematological effects, reproductive dysfunction, sensory and equilibrium disturbances, hyperactivity, aggressiveness, impairment of peripheral vision, impairments

192. Id. at 15,368-15,371.

193. Id. at 15,381.

194. See Annex C, row 70.

195. Id. at 15,382 and Hahn spreadsheet, Row 9, columns BH-BT [unpublished spreadsheet on file with the author]. The manipulation reflected in those columns involves discounting the number of lives saved to reflect the assumed latency period of cancer, and valuing those lives at the standard value assigned by Hahn as opposed to the range of values chosen by the agency.

of hearing and speech, etc.[196] EPA emphasized the special risks to children since these toxins accumulate in mother's milk: possible low birth weight, small head circumference, skeletal anomalies, malformations such as scoliosis, cranio-facial abnormalities, delayed bone development, and so forth. The agency also mentioned impacts of bio-accumulative toxins on a range of non-human animals and plants.[197]

However, the agency's assessment offers no indication of whether the probabilities of such impacts are high, medium or low or how widespread or severe such impacts might be. The rule was not considered a "major rule" in any case (because of its small economic impact), and both the rule and the benefits information it contained were excluded from Hahn's database (which excludes all but cancer, heart-disease and lead-related benefits).

The fact remains: if all these non-cancer and ecological benefits existed for the mixing zone rule, they must certainly also have existed for the main water quality guidance issued four years earlier. Why did EPA not *mention* (much less attempt to quantify) such benefits then? It cannot be the case that the benefits were discovered after the original rule. The health and eco-system risks of persistent bio-accumulative chemicals have been generally known since Rachel Carson's best-selling expose, Silent Spring, was published in 1962.[198] Indeed, the chemicals addressed by the guidance include several of the very same chemicals – DDT, chlordane, dieldrin, heptachlor – than Carson campaigned against forty years ago. EPA deserves some blame for a characterization of risk and benefit that was perfunctory at best. But even the most detailed narrative description of risk would have made no difference to the scorecards, which are equipped to deal only with numbers.

Requiring proper handling of toxic petroleum refinery sludge. Oil refineries around the country generate between 150,000 and 300,000 tons of sludge every year – sludge which contains lead, chromium, arsenic, benzene, toluene, benzo(a)pyrene and several other known poisons at "concentrations that are tens to thousands of times higher than standard EPA health-based and ecological protection reference levels."[199] According to EPA, this toxic sludge is quite often stored in unlined pits upgradient from wells and rivers or over "relatively shallow aquifers" causing contamination to spread considerable distances underground. In 1990, EPA issued a rule officially classifying this sludge as hazardous waste – a move that ended the practice of (legally) storing sludge in unlined ponds.[200] Henceforth, oil refineries would have to properly manage their toxic sludge, through incineration,

196.   Proposal to Amend the Final Water Quality Guidance for the Great Lakes System to Prohibit Mixing Zones for Bioaccumulative Chemicals of Concern, 64 Fed. Reg. 53,632, 53,638-53,639 (1999).

200.   Id.

treatment, or storage in sealed containers, "or by some other means that precludes the migration of toxic pollutants into ground waters or surface waters."[201]

The common sense of this rule is so manifest that one might reasonably wonder why EPA should have been forced to undertake a massive study in order to justify it. Nonetheless, EPA dutifully performed the required Regulatory Impact Assessment to examine both the costs and the benefits of the rule. That assessment perfectly illustrates the epistemological hierarchy discussed earlier.

On the benefit side, EPA undertook a detailed exposure and risk assessment for people living down gradient from oil refineries – something which was not done in the waste combustor rule examined above. The risk assessment predicted that baseline (pre-rule) practices were causing one to three cancer cases per year, with the risks to the most exposed individuals ranging from 1/10,000 to an alarming 1/100.[202] In addition, EPA concluded that 6,400-32,000 people could be exposed to drinking water concentrations of lead and/or chromium in excess of their respective health effect thresholds, thereby incurring risks of kidney and/or liver damage from chromium ingestion as well as neuro-toxicological damage from lead.[203] However, EPA was unable to ascertain – on the basis of reliable scientific data – either the probable number of non-cancer health harms or their severity. Nor was EPA able to predict the non-carcinogenic health effects, if any, from the other toxins mentioned. The ecological benefit of the rule gets one sentence:

> "An additional benefit, not quantified in this RIA, is that pollutant loadings to surface waters and wetlands through groundwater migration and transport at 56-102 refineries (about 75 percent of sludge generators) should also be substantially reduced or eliminated as a result of this rule."[204]

At the end of the presentation of its findings, EPA offers something that all regulatory assessments should provide: a Summary of Analytical Limitations and Qualifications. EPA first lists the factors that tend to over-estimate benefits: for example, the agency employed conservative groundwater transport and dose-response models which might tend to over-state risk. In addition, EPA assumed that down gradient people who get their water from wells would drink 2 liters of untreated water per day, and that all wells within a specified distance down gradient from the refinery would be contaminated. This is, of course, a very conservative assumption, as is the assumption that no other federal, state or local regulations would intervene to mitigate harm.[205]

---

201. Id. at 46,392.

202. Id. at 46,391.

203. Id. at 46,392.

204. Id. at 46,393.

205. Id at 46,393 - 46,394.

On the other hand, EPA made a number of assumptions which it thought "may tend to underestimate benefits."[206] For example, the agency examined the effects of only a few of the many toxic chemicals present in oil refinery sludge. EPA ignored background exposures which might add to the harm of refinery exposures. EPA considered one exposure pathway (drinking), while ignoring inhalation, dermal contact, and the risk of food chain contamination from using contaminated surface water to irrigate crops.[207] No ecological damages were quantified, even though, in EPA's words,

> "surface waters exist downgradient within 1200 meters at 75 percent of refineries and that other wetlands (swamps, bogs, etc) are equally nearby at over 25 percent of refineries. [Moreover] . . several chemicals present in the sludge are known to bioaccumulate and/or concentrate in the benthic layers which is critical to the invertebrate elements of the food chain."[208]

Such disclaimers are both reassuring and exasperating. Reassuring because they are relevant and honest. Exasperating because they do not tell the decision-maker what she needs to know: is the agency assessment, on balance, an over-estimate, under-estimate or reasonably accurate estimate of the benefits of the rule?

Hahn is not troubled by such Gordian knots. He simply assigns the entire rule a zero benefit.[209]

e. *Statutorily mandated benefits*

Risk assessments and cost-benefit analyses can be extraordinarily time consuming and expensive, without necessarily yielding a clear picture of costs and benefits at the end of the day. Agencies are understandably reluctant to spend vital agency resources – and taxpayer dollars – perfecting such assessments when Congress has already made the relevant determination on other grounds, or has ordered the agency to make the determination on other (e.g. health or technology-based) grounds. Two examples will serve to illustrate what happens when agencies try to save money and time in such circumstances.

The SARA Implementation Rule. In 1990 EPA promulgated a rule revising the National Contingency Plan to implement the Superfund Amendments and Reauthorization Act of 1986 (SARA).[210] SARA

---

206. Id. at 46,394.

207. Id.

208. Id.

209. Annex C, row 85.

210. National Oil and Hazardous Substances Pollution Contingency Plan: Final Rule, 55 Fed. Reg. 8,666 (March 8, 1990)[hereinafter SARA Rule]. For Hahn's treatment of the same rule see Annex C, row 66.

established, among other things, a presumption in favor of cleaning up hazardous waste sites, rather than simply building perimeters around them.

EPA's offers no published explanation of the benefits of this rule apart from a reference to an unpublished consultant's report buried in EPA's docket room.[211] The agency did, however, devote three Federal Register pages to the estimated *costs* of the rule.[212]

EPA gave two reasons for failing to quantify the benefits of this rule. First, "[c]urrent program information was insufficient in several areas necessary to develop reasonable estimates of quantified benefits" for each of the several thousand individual waste sites scattered around the country.[213] Second, the rule was statutorily mandated in any case, meaning that the relevant cost-benefit determination had already been made – by Congress.[214] Under these circumstances, EPA concluded that the benefits of a ful cost-benefit analysis did not justify the high analytical costs.[215]

The result in Hahn's scorecard: a $21 billion cost and zero benefit.[216]

Water pollution standards for the Electroplating and Metal Finishing Industries. In 1983, EPA issued a rule setting forth effluent limitations guidelines, pretreatment standards and new source performance standards for electroplating and metal finishing point sources under the Clean Water Act.[217] The preamble to the rule contains a section entitled "Costs, Effluent Reduction Benefits, and Economic Impact" which devotes several pages to

---

211. SARA Rule, *supra* note 210, at 8,811 (citing EPA, Policy and Analysis Staff, Office of Solid Waste and Emergency Response, Regulatory Impact Analysis in Support of the Proposed Revisions of the National Oil and Hazardous Substances Pollution Contingency Plan Docket No. NCP-R2-8-1 (Sept. 1988) (unpublished manuscript on file with the author) [hereinafter Proposed SARA Rule Staff Analysis]). The benefits mentioned in that report include: reduced health hazards from exposure to waste migrating off-site; recreation benefits from cleaner water off-site; the option value of clean water; and a reduced challenge to containment in later years. Proposed SARA Rule Staff Analysis, *supra* at 3-24, 3-25.

212. SARA Rule, *supra* note 210, at 8,810 - 8,812.

213. USEPA, Policy and Analysis Staff, Office of Solid Waste and Emergency Response, Regulatory Impact Analysis of Revisions to CERCLA and the National Contingency Plan 1-1 to 1-2 (Nov. 1989) (unpublished manuscript on file with the author).

214. In EPA's words: "This report also does not present a formal benefits analysis . . . Because the Superfund is financed by a tax authorized by Congress, Congress determined implicitly that the benefits of cleaning up hazardous waste sites were worth the expenditures of the Superfund." Proposed SARA Rule Staff Analysis, *supra* note 211, at 1-2.

215. Though EPA did not mention it overtly as a reason for not quantifying benefits, it seems clear that another reason for not quantifying the benefits of the SARA Rule is found in the fact that the rule is really a procedural rule. In essence, the rule establishes a presumption in favor of treatment, which may be reversed on the basis of later (and much more manageable) risk assessment and cost-benefit analysis of options for handling each individual site. As seen above, the benefits of procedural rules are difficult, if not impossible, to quantify. See discussion *supra*, Section II.A.1.b.

216. See Annex C, row 66.

217. Electroplating and Metal Finishing Point Source Categories: Effluent Limitations Guidelines, Pretreatment Standards and New Source Performance Standards, 48 Fed. Reg. 32,462 (1983).

a summary of a lengthy, quantitative analysis of the costs of the rule, followed by exactly three sentences on the benefit:

> The Agency concludes that the final regulation is economically achievable, and the impacts are justified in light of the effluent reductions achieved. The metal finishing regulation will remove an additional 20 million pounds per year of metals and cyanide and 10 million pounds per year of toxic organics. . . . Executive Order 12291 does not require a [full-blown] Regulatory Impact Analysis where its consideration would conflict with the development of regulations pursuant to a court order, as with this metal finishing regulation."[218]

The result in Hahn's scorecard: a $4 billion cost (over twenty years), a zero benefit, another failed regulation.[219]

f. *Indirect costs and cost savings*

The scorecardists' omission of unquantified variables is not confined to the benefits column. Economists have long recognized that government regulations bring with them an array of indirect costs and cost savings that tend to be overlooked to varying degrees in agency RIAs and scorecards alike.

The list of omitted indirect costs includes: (1) government costs of monitoring, inspection, record keeping; (2) corporate costs for legal advice, shifted management focus, disrupted production, and diverted investment; and (3) consumer price increases, welfare loss from product substitution, possible unemployment or wage reduction, diminished returns to shareholders on invested capital, and/or retarded product innovation.[220]

Regulations may also generate cost *savings* through: (1) stimulation of product or process innovation to minimize waste; (2) improvements in worker health and productivity; and/or (3) reduction or avoidance of liability for damages.[221]

How important are these omitted costs and cost savings? Because indirect costs are seldom discussed in agency regulatory analyses, they cannot be readily illustrated with narratives drawn from the preambles of rules, as the previous discussion has done for unquantified benefits. However, some insight into their nature and likely magnitude can be gleaned from the extensive literature on the link between regulation and

---

218. Id. at 32,472(emphasis supplied).

219. See Annex C row 76. See also Double Hull Rule, *supra* note 165 at 2 ("This environmental evaluation makes only a limited assessment of the specific environmental consequences of the double hull construction requirement since, even without this rule, double hull construction is required by the existing statute.").

220. Adapted from Jaffe, *supra* note 78, at 139, tbl. 9. Obviously, these are *categories* of potential cost or cost saving. They do not necessarily apply to every regulation or industry, and they certainly do not apply equally to all.

221. Id.

"competitiveness" – a linkage which captures the net effect of most of the direct *and* indirect costs and cost savings of interest here.[222]

In an important survey of the empirical work on point, Jaffe et al concluded that "overall, there is relatively little evidence to support the hypothesis that environmental regulations have had a large adverse effect on competitiveness, however that elusive term is defined."[223] One major reason for this slight impact, according to the authors, is that direct compliance costs are extremely low as a percentage of production costs – less than 2 percent of the value of shipments in industries with "high abatement costs" and less than one half of one percent of the value of shipments in other industries.[224] Most *indirect* costs – such as loss of productivity, employment, price increases, loss of consumer welfare – are derivative of *direct* compliance costs. Therefore, one would expect low direct costs generally to produce low indirect costs as well, yielding a low competitive and consumer impact overall.[225]

Professors Michael Porter and Claas van der Linde attracted a great deal of attention a decade ago when they advanced the thesis that environmental regulations, at least, may actually *enhance* corporate competitiveness (and, by extension, consumer or shareholder welfare) by providing management an incentive to re-examine and re-engineer their production process with health, safety, resource conservation and waste reduction in mind.[226] While mainstream economists have viewed the so-called "Porter hypothesis" skeptically – it rests principally on anecdotal evidence and implies that firms are ignorant of opportunities to increase

---

222. See Jaffe, *supra* note 78 at 138-139 (citing costs listed above as indicative of potential impacts on "competitiveness"). Jaffe claims that there are over 100 studies of the regulation - competitiveness link as of 1995. Id. at 135. The two categories not conceptually encompassed by the "competitiveness" impacts are government costs and consumer impacts. Government costs are hard to measure because salaried legislators and regulators perform a range of law-making, monitoring and enforcement functions which vary widely, in their particulars, from year to year. It is therefore extremely difficult to allocate their collective salaries to any particular activity. However, government costs of monitoring and enforcement are generally thought to be small relative to overall costs of compliance. Morgenstern, Richard D. et al, The Cost of Environmental Protection, RFF Discussion Paper 98-36, 9 (May 1998). Consumer impacts, though conceptually different from competitiveness impacts, probably move in parallel with such impacts in the sense that both arise mainly from direct compliance costs in the first instance.

223. Jaffe *supra* note 78 at 157.

224. Id. at 141 tbl. 6.

225. In addition, indirect regulatory costs can be hard to identify, particularly in cases where firms respond to regulations by changing their products or production processes to reduce the generation of waste. The cost of efficiency-enhancing changes may or may not be captured as a regulatory compliance cost, and the efficiencies that result may or may not be captured as an environmental cost saving. As Jaffe puts it, "we may have found little relationship between environmental regulations and competitiveness simply because the data are of poor quality." Id. at 158.

226. Michael E. Porter, The Competitive Advantage of Nations (1990); Michael E. Porter & Class van der Linde, Toward a New Conception of the Environment-Competitiveness Relationship, 9 J. Econ. Perspectives 97 (1995).

profits until a regulation comes along[227] – what is important for present purposes is what is *not* disputed: the competitive impacts (and, by inclusion, the indirect impacts) of regulation are generally small.[228] There is no evidence that omitted costs simply cancel out omitted benefits, thereby excusing the disregard of both. That would be a remarkable coincidence, indeed.

Nonetheless, the scorecardists' omission of unquantified costs in scorecards is more understandable than their treatment of benefits in one respect: agencies do not normally offer a narrative description of the various costs that are being overlooked in particular cases. So at least scorecards are not *distorting* agency analysis – while claiming to summarize it – when they fail to mention unquantified costs.

g. *Risk-risk tradeoffs*

In addition to their monetary costs, risk-reducing regulations may create new risks of their own. Professor Sunstein has compiled numerous examples of these "ancillary risks."[229] Fuel economy standards, designed to make reduce environmental risks, may make cars smaller and less safe. Removing contaminated soil from Superfund sites creates the possibility of accidents in transit or contamination of the site to which the soil is removed. The intense regulation of nuclear power has encouraged a shift to coal, which has

---

227. See Jaffe, *supra* note 78 at 155. In a 1995 article devoted to rebutting the Porter hypothesis, Palmer, Oates, and Portney reported the results of telephone interviews with vice presidents or corporate directors for environmental protection at four firms cited by Porter and van der Linde: "While each manager acknowledged that in certain instances a particular regulatory requirement may have cost less than expected, or perhaps even paid for itself, each also said quite emphatically that, on the whole, environmental regulation amounted to a significant *net* cost to his company." Karen Palmer, Wallace E. Oates, & Paul R. Portney, Tightening Environmental Standards: The Benefit-Cost or the No-Cost Paradigm?, 9 J. Econ. Perspectives 119, 127 (1995). The authors also reported the results of a Census Bureau Survey of manufacturers which specifically asked respondents to estimate both their pollution abatement and control expenditures and the "cost offsets" (i.e. cost savings) associated with these expenditures. In 1992, the expenditure estimates totaled $102 billion while the cost savings amounted to $1.2 billion, less than 2 percent of estimated environmental expenditures. Id. at 127-128.

Of course, surveys of corporate executives are not necessarily dispositive of the issue. Capital and operating costs of pollution control equipment are readily apparent to managers while any cost savings associated with a product or process change appear nowhere on the balance sheet or income statement of the corporation, and therefore tend to recede from memory. Under such circumstances, it would hardly be surprising if corporate managers tend to under-estimate cost savings when asked for an off-the-cuff opinion in a telephone survey. In the last analysis, as Jaffe concedes, while Porter has not proved his hypothesis, economists have not marshaled the hard empirical evidence necessary to refute it either. See Jaffe *supra* note 78, at 157. ("While economists have good reason to be skeptical of arguments based on non-optimizing behavior where the only support is anecdotal, it is also important to recognized that if we wish to persuade others of the validity of our analysis we must go beyond tautological arguments that rest solely on the postulate of profit-maximization.")

228. See Jaffe, *supra* note 78 at 157. However, as Jaffe emphasizes earlier in the same review, his analysis is limited to the manufacturing sector. The competitive impacts of regulation may loom considerably larger in the (much less examined) natural resource extraction sectors: forestry, fishing, mining, oil extraction, etc. Id. at 136.

229. Health-Health Tradeoffs, *supra* note 15, at 1535.

aggravated acid rain and global warming.[230] Some economists have argued that even the funds expended to comply with regulations reduce the sum of money available for life-saving health care, thereby costing statistical lives. Proponents of this view argue that the value of lives lost by regulation through the income effect ought to be deducted from the life-saving benefits of regulation.[231]

Sunstein also has compiled a number of reasons, good and bad, for agencies' failure to quantify such risk-risk tradeoffs in their regulatory assessments. Agencies may be unaware of the ancillary risk. The ancillary risk may fall outside the agencies' expertise or jurisdiction. Some statutes bar agencies from considering ancillary risks in certain decisions. The agency may find the ancillary risk too complex or too speculative to warrant a major delay in the regulation of the primary risk. Of course, agencies may sometimes ignore ancillary risks out of simple myopia, or in capitulation to special interests or irrational public pressures, or out of a desire to bolster the regulatory record supporting a preferred primary regulation.[232]

Whatever the reason, risk-risk tradeoffs are typically slighted in agency assessments and scorecards alike. These trade-offs count as unquantified "costs" of regulation, the omission of which tends to *over-state* the net benefits of regulation.

2.   *Are these exclusions defensible?*

---

230.   These and many other examples may be found in Id. at 1535, 1536, 1556.

231.   Id. at 1543-1551,1562 (surveying large literature devoted to assessing the claim that regulatory expenditures can cost lives and calling for courts to adopt an interpretive principle that agencies can incorporate assessment of health-health tradeoffs in decision-making absent a clear legislative statement otherwise). While few would dispute the existence of physical risk-risk tradeoffs, the idea that regulatory expenditures costs lives *per se*, is hotly contested on at least three grounds. First, it is obviously counter-intuitive. Second, it rests on empirical studies of questionable validity which generally correlate higher income with lower mortality and then assume, illogically, that higher income somehow causes lower mortality. (In fact, both may correlate with some omitted third factor, such as education levels.) For a critique of the empirical basis of the expenditure-mortality link, see Smith, V. Kerry, Donald J. Epp, and Kurt A. Schwabe, Cross-Country Analyses Don't Estimate Health-Health Responses, in The Mortality Costs of Regulatory Expenditures: A Special Issue of the Journal of Risk and Uncertainty, 8 J. Risk & Uncertainty 67 (W. Kip Viscusi, ed., 1994). Third, simply as a logical matter, it is highly implausible to suggest that regulatory expenditures amounting to, at most, a few percent of disposable income could so reduce discretionary income as to deny people access to life-saving health care to a degree that would implicate their longevity. Such a causal nexus is plausible, if at all, only for poor people with no access to health insurance or subsidized care, who are subject to significant regulatory costs, either directly or indirectly through higher-priced goods. No empirical studies of which this author is aware have documented the existence of such a confluence of circumstances. Ultimately, then, the regulatory expenditure-mortality link rests on little more than a suggestive statistical correlation that lacks grounding in a persuasive model of causation. Moreover, if lack of adequate access to health care is source of mortality and access to good health care is the goal, it makes far more sense to reform our medical system to directly ensure such access, rather than to try to achieve the same goal indirectly, through an attenuated and speculative link to regulatory reform. See, Portney, Paul R. & Robert N. Stavins, Regulatory Review of Environmental Policy: The Potential Role of Health-Health Analysis, in The Mortality Costs of Regulatory Expenditures: A Special Issue of the Journal of Risk and Uncertainty, 8 J. Risk & Uncertainty 111 (W. Kip Viscusi, ed., 1994).

232.   Health-Health Tradeoffs, *supra* note 15, at 1555-1557.

One possible line of defense to the exclusion of significant costs and benefits in scorecards may be to argue that it is not the scorecardists' fault. If the government does not bother to quantify and monetize the benefits of the regulations it enacts what is the scorekeeper supposed to do? The agency, on this view, holds the keys to its reputation in its own hand.

There are at least three main problems with this line of defense. The first is that, as we have seen, current scorecards do not always count even the benefits that agencies have monetized.[233]

The second problem with the only-numbers-matter theory is that it is flatly inconsistent with what the scorecardists publicly claim they are offering. Whatever the reason for the government's failure to assign a number to all costs and benefits, one cannot claim to have discerned "the" costs and benefits of a regulation while excluding whole categories of unmeasured costs and benefits. And one certainly cannot claim to be using the "government's numbers" while supplying streams of zeroes that are found nowhere in any agency analysis. When a scorekeeper assigns a "zero" to a benefit that an agency described but lacked data to quantify or monetize, that zero is not the government's number. That is the score keeper's number.

The third, and most fundamental, problem with numbers-only scorecards is that not all costs and benefits can be reduced to numbers, certainly not to numbers that are empirically defensible. In most cases, launching a regulation marks the beginning of an exploration of territory that is scientifically and economically unknown. Therefore, rule analyses are not and cannot be what scorecardists implicitly assume they are and must be: final declarations of exactly what one will find at the end of the process. That is why a cardinal principle of cost-benefit analysis holds that:

> "not all impacts of a decision can be quantified or expressed in dollar terms. Care should be taken to assure that quantitative factors do not dominate important qualitative factors in decision-making."[234]

No one disputes this principle.[235] Scorecards simply do not practice it.

Of course, scorecardists cannot be expected to factor into their analysis information of which regulatory evaluators are themselves unaware. If EPA is ignorant of the existence of water pollution risks of MBTE when it issues its regulation requiring that fuel additive, one cannot reasonably expect Robert Hahn to include them in his scorecard. Unidentified costs and benefits plague *every* mode of regulatory analysis.

The culpability of scorecards is found, not in their failure to detect previously unidentified costs and benefits, but in their omission of costs and benefits which agencies identify and describe narratively, but do not pretend to be able to quantify or monetize. These are the omissions that violate cardinal principles of cost-benefit analysis, that are unique to scorecards, and

233. See discussion *supra* Section II.A.1.a.

234. Annapolis Principles, *supra* note 111, at 10.

235. Indeed, Hahn is a co-author of these very words. See list of authors of Annapolis Principles, *supra* note 111.

that call the viability of scorecards into serious question.[236]

Could better scorecard methodology avoid such problems? The answer is clearly no. The point of scorecards, after all, is to come up with the number of rules that generate positive net benefits, or that cost less than some threshold amount per life saved. Without the numbers, how does one keep score?

The dilemma facing scorecards is well illustrated in OMB's Annual Report to Congress on the Costs and Benefits of Federal Regulations.[237] Each year OMB compiles its estimates of the costs and benefits of regulations. Unlike the scorecards discussed in this article, however, OMB also includes a column entitled "Other Information" in which unquantified costs and benefits are narratively described.[238] These entries, of course, preclude final declarations about whether the rules in question pass or fail cost-benefit tests, and OMB therefore offers no statistic on that point. OMB has avoided the problem of ignoring un-enumerated benefits but, in so doing, has surrendered the function of a scorecard. OMB's candor also comes at the price of quotability: no surprise, OMB's reports have received far less media coverage than the more sensational scorecards.[239]

---

236. Almost as troubling as the fact of such omissions is the scorecardists' failure to disclose them properly. Hahn makes no mention in his Executive Summary of the fact that whole categories of health and non-health benefits have been zeroed out in his analysis. One must read the fine print of his methodology section, the footnotes and the unpublished spreadsheet (along with the preambles to the rules referenced in the spreadsheet) to appreciate the significance of what Hahn is not counting. See e.g., Government's Numbers (2000), *supra* note 13, at 94. n. 71: "I included only air pollution reduction benefits because the agencies did not generally quantify any benefits from pollution reduction other than from air pollution reduction [Not true – see *infra* Section II.A.1.a.] According to EPA, those [unquantified] benefits are large and may therefore significantly affect the results of the regression. Pollution reduction benefits can change the cost-effectiveness estimates by orders of magnitude and in some cases can even change the sign of the estimates." Unfortunately, Hahn's public presentation of his results has never, to my knowledge, been accompanied by a similar caveat.

Graham and Tengs acknowledge – once, in the penultimate paragraph of Five-Hundred Interventions – that "we recognize that many of these interventions have benefits other than survival." Five Hundred Interventions, *supra* note 9, at 372. This recognition, unfortunately, does not lead to any exploration of its logical implications.

Morrall points out, once in passing, that "many regulations were projected to yield benefits in addition to saving lives, such as reducing non-fatal injuries and property damage." He claims that he "accounted for" these benefits by "converting non-lifesaving health benefits into an index equivalent to additional lives saved . . . 50 non-fatal hospitalizations avoided, or two permanent disabilities avoided, were assumed to be equivalent to one death avoided." Morrall, *supra* note 8, at 28. But he does not count non-health benefits at all. Nor does he tally health benefits other than those which avoid hospitalization or permanent disability. And he offers no explanation of the rationale, if any, that underlies his seemingly arbitrary illness/fatality conversion ratios.

237. See, e.g., OMB, Making Sense of Regulation: 2001 Report to Congress on the Costs and Benefits of Regulations and Unfunded Mandates on State, Local and Tribal Entities (2001).

238. Id. at 22-28, tbl.4.

239. A recent Lexis search of the Lexis Major Paper database turned up a total of eight cites to OMB annual reports over a period of eight years. Of these, six are by Cindy Skrzycki of the Washington Post and two are in other publications. Moreover, the main message of these articles tends to be, not the horrors of regulation, but the difficulty of

The discussion so far has focused on the exclusion of intangibles because it is perhaps the most serious of the inherent problems of method that scorecards confront. But it is by no means the only one. Additional trade-offs between brevity and realism can be found in the way scorecards deal with distributive impacts.

B. *Disregarding distributive impacts*

A particularly telling criticism of cost-benefit analysis is its tendency to overlook the distributive and equitable impacts of regulatory decisions.[240] This section will show that while cost-benefit analysis is in principle capable of both considering and deferring to such concerns, scorecards are inherently *incapable* of doing so.

Most cost-benefit analyses treat risks and costs as fungible commodities whose distribution can be largely ignored. The lives saved are statistical lives, the resources expended are society's resources. Indeed, this author found no formal discussion of distributive impacts in *any* of the regulatory impact analyses cited in this article.

In purely statistical terms, a 1:100,000,000 risk imposed involuntarily on ten million people is statistically interchangeable with a 1:10 risk of death imposed involuntarily on a single person. Common sense and basic fairness suggest otherwise. If a 1:1,000,000 risk is a tiny and widely dispersed risk which seems a reasonable price to pay for benefit of modern living (assuming the activity brings a clear benefit), a 1:10 risk of death is essentially a game of Russian roulette which society has no *right* to force anyone to play for any amount of social economic gain. Likewise, though the point is more debatable, a regulation that costs a million consumers a dollar each is probably preferable to one of similar aggregate cost that eliminates one hundred jobs. Analysis which fails to consider the distribution of impacts (be they costs or benefits) misses an important part of the picture.

Closely related to the distribution of impacts are questions about the identity of the risk or cost bearers. Once again, aggregate statistics conceal potentially important issues of who pays the cost of regulation, and who benefits. Some would argue that a risk that falls disproportionately on the minorities or the poor (who often lack adequate access to health care) should

239. (...continued)
measuring costs and benefits accurately. See Cindy Skrzycki, The Regulators Pencils Sharpened: OMB to Revisit Costs, Benefits of Rules, E01, Wash. Post E01 (May 29, 2001); Cindy Skrzycki, Paying by the Rules; OMB's Cost Analyses Questioned, Wash. Post, E01 (Feb. 4, 2000); Cindy Skrzycki, The Regulators: The Costs and Benefits of Cost-Benefit Analysis, Wash. Post E01 (Aug. 6, 1999); Cindy Skrzycki, OMB Tries to Add Up the Bill for Federal Rules, Wash. Post E01 (Feb. 12, 1999); Cindy Skrzycki, The Regulators: an 'Independent' Center Opens: Bringing Brainpower to the Commentary on Rules, Wash. Post G01 (Oct. 9, 1998); Cindy Skrzycki, The Regulators: A Chairman's Ire, Stacks and Stones at the Labor Relations Board, Wash. Post G01(Oct. 31, 1997); Bonner R. Cohen, Lawmakers target the regulatory monster, J. Commerce 9 (Jun 3, 1999); Murray Weidenbaum, Opinion/essays; Column: Streamlining The Regulatory Tangle, The Christian Science Monitor 19 (May 21, 1998).

240. See, e.g., Pricing the Priceless, *supra* note 38, at 23-25 (noting that a "fundamental defect" of cost-benefit analysis is that it tends to ignore, and therefore to reinforce, patterns of economic and social inequality" while disregarding "questions of rights and morality" that are not reducible to monetary terms).

be weighted more heavily, other things equal, than one whose burdens are more equitably distributed. Likewise, some assert that a regulation whose costs fall disproportionately on the poor should be registered as more "costly" than a regulation which that does not place additional burdens on the poor or disadvantaged.[241]

Others (principally economists of a certain stripe) insist that regulations which disproportionately benefit the poor, the aged, or the afflicted should be assigned a *lower* value than those favoring the well-off, the young and the healthy.[242] The fact that this debate is not an inch closer to resolution today than it was ten years ago must count as a major embarrassment to defenders of the genre. Yet no one seriously alleges that the question of who benefits from, or bears the cost of, regulation is a matter of indifference.

Single rule analyses are able, in principle at least, to take account of the distribution of impacts of individual regulations. Indeed, widely agreed canons of cost-benefit analysis call on analysts to examine distributive impacts wherever they are significant – though actual examples of this happening are rather hard to find.[243] In any case, proponents of cost-benefit analysts recognize that considerations of "right" and distributive "fairness" ought to be considered side by side with utilitarian arguments. And they recognize that the former may, on occasion, trump the latter.[244]

---

241. EPA EA Guidelines, *supra* note 96, at 139-171 (calling for analysis of the impact of regulatory costs on employment, profitability, plant closure, competitiveness, and small businesses, as well as "disproportionate" impacts on minorities, low-income populations, children, and any risk to individuals "above generally accepted norms" – but without identifying any weighting mechanism to reflect distributive justice concerns).

242. See, e.g., W. Kip Viscusi, Equivalent Frames of Reference for Judging Risk Regulation Policies, 3 N.Y.U. Envtl L. J. 431, 447 (1994) ("[T]he United States Department of Transportation should want to place a higher value on the well-being of the lives of airline passengers than those killed in motor vehicle crashes because the airline passengers have a higher income"). Lawrence Summers, then chief economist at the World Bank and the current president of Harvard University, wrote in 1991, "The measurements of the costs of health impairing pollution depend . . . on the foregone earnings from increased morbidity and mortality. From this point of view a given amount of health impairing pollution should be done in the country with the lowest cost, which will be the country with the lowest wages. I think the economic logic behind dumping a load of toxic waste in the lowest wage country is impeccable and we should face up to that." Internal World Bank Memo, available at www.whirledbank.org/ourwords/summers.html, and reproduced in Pricing the Priceless, *supra* note 38, at 24. Heinzerling elsewhere observes, astutely, that the recent emphasis on measuring "Quality-Adjusted Life Years (QALY)" preserved, rather than live saved, is a backhanded way of privileging the young, the well-off, and the healthy over the older, the poor and the infirm. See Rights of Statistical People, *supra* note 90, at 193.

243. See Annapolis Principles, *supra* note 111, at 8 ("a good cost-benefit analysis will identify important distributional consequences of a policy"); OMB Guidelines, *supra* note 89, at 16 ("If . . . distributive effects are important, you should describe the effects of various regulatory alternatives quantitatively to the extent possible, including their magnitude, likelihood, and incidence of effects on particular groups."); EPA EA Guidelines, *supra* note 96 (devoting Chapter 9 to guidance for conducting distributional analyses).

244. See Annapolis Principles, *supra* note 111, at 7 ("Agencies should not be bound by a strict benefit-cost test . . . There may be factors other than economic benefits and costs that agencies will want to weigh in decisions, such as equity within and across generations."); Robert M. Solow, Reply to Steven Kelman, Cost-Benefit Analysis: An Ethical Critique, in Economics of the Environment: Selected Readings 367, 368 (Robert N. Stavins ed., 4th ed. 2000) ("Treatises on the subject make clear that certain ethical or political

(continued...)

Given this recognition, it is not quite fair to assert that cost-benefit analysis inherently requires the wholesale subordination or obfuscation of equitable concerns. But it is fair and, indeed, necessary to say that the scorecards discussed in this Article pay absolutely no attention to the distribution of cost or risk in society, or to any ethical concerns, and it is hard to see how they could. The scorecard enterprise by its very nature requires tabulating costs-per-life-saved or net benefits across large numbers of rules, and then compressing the tabulation into a few summary statistics. This renders it difficult if not impossible for scorecards to take account of differences in the distribution of risks, costs or benefits. The enormity of the task facing scorecards will become even more evident when we turn to the treatment of uncertainty.

C. *Concealing uncertainty*

One of the most striking features of the Hahn, Morrall and Graham//Tengs scorecards – and, one suspects, a key to their great influence – is the precision of their numbers, which they typically report to three or four significant digits.[245]

Yet the appearance of precision is highly misleading. A large, though esoteric, literature already documents the data gaps and other uncertainties confronting efforts to estimate, and then monetize, physical risks to human health and eco-systems.[246] A growing literature attests to the huge uncertainties facing regulatory cost predictions as well.[247] Yet scorecardists

---

244. (...continued)
principles may irreversibly dominate the advantages and disadvantages capturable by cost-benefit analyses).

245. See, e.g., Government's Numbers (2000), *supra* note 13 at 43, tbl 3-5, reporting the net benefits of final rules promulgated under the Clean Air Act, 1981-mid-1996 at $586.9 billion. How, one wonders, can he be so sure that they are not $587.2 billion? Or $627.4 billion? Or any number between, say, $500 billion and $700 billion? Graham and Tengs inform the reader at one point that "all estimates are rounded to three significant digits to stress their approximate nature." Opportunity Costs, *supra* note 10, at 182, note 1. The authors apparently fail to realize that "rounding to three significant figures" implies accuracy to one-tenth of one percent.

246. See, e.g., William D. Ruckelshaus, Risk in a Free Society, 14 Envtl. L. Rep. 10190, 10190-10191 (1984) (discussing the difficulties of extrapolating low-dose human risks from high-dose animal test, and of establishing that any particular has caused a particular human harm). See also generally John Dwyer, Limits of Environmental Risk Assessment, 116 J. Energy Engineering, No. 3 (1990); Mark Eliot Shere, The Myth of Meaningful Environmental Risk Assessment, 19 Harv. Envtl. L. Rev. 409 (1995); David D. Doniger, Federal Regulation of Vinyl Chloride: A Short Course in the Law and Policy of Toxic Substances Control, 7 Ecol. L. Q. 500, 508-14 (1978) (discussing the myriad difficulties in assessing cancer risks and documenting the wide divergence in risk estimates stemming from extrapolation studies); and Celia Campbell-Mohn & John S. Applegate, Learning from NEPA: Guidelines for Responsible Risk Legislation, 23 Harv. Envt'l. L. Rev. 93, 99-102 (1999) (providing a concise account of the literature on the scientific limitations of risk assessment and documenting the practical difficulties in obtaining data from regulated entities).

247. It is generally known, for example, that indirect and/or unanticipated costs tend to increase burdens above expected levels; while learning curves, economies of scale and corporate innovations tend to constrain cost impacts and may, on occasion, even improve

(continued...)

present their results (particularly in the media) with the routine confidence of a draper measuring curtains.[248]

The scorecardists' failure to disclose uncertainties fully cannot be excused by weaknesses in agency assessments. Agencies quite often report ranges of estimates and disclose major sources of uncertainty in their estimates, in keeping with good practice.[249] It is the scorecardists who largely omit this important step.

Again, basic principles of cost-benefit analysis require full documentation of major sources of uncertainty, with sensitivity analysis to explore the impact of altering fundamental assumptions.[250] The authors of

---

247. (...continued)
productivity. Jaffe, *supra* note 78, at 139-140 (offering taxonomy of direct and indirect costs and cost savings and noting that "[e]ven estimates of direct, compliance expenditures vary greatly"). See also Harrington, *supra* note 67 (cataloguing unreliability of existing cost estimates and sources of cost estimation errors); McGarity and Ruttenberg, *supra* note 32; Goodstein and Hodges, *supra* note 31; Driesen, *supra* note 82 at 600-601; Kammit, James K., Are the Costs of Proposed Environmental Regulations Overestimated?: Evidence from the CFC Phaseout, 00 Envt'l and Resource Econ. 1 (1999); Cindy Skrzycki, The Regulators Pencils Sharpened: OMB to Revisit Costs, Benefits of Rules, E01, Wash. Post E01 (May 29, 2001) (noting that OMB report on costs and benefits of regulation "gave some insight into how difficult it is, even for the pros, to do the math on the exact magnitude and cost of regulation.")

248. Hahn's own writings in the Washington Post perfectly exemplify the way his and other scorecardists' conclusions are routinely presented in the media: "[m]any of the regulations that deal with the environment, health, safety and employment . . . meet this common-sense test [of benefits exceeding costs]. But many don't. By our estimate, more than half the social regulations issued between 1982 and mid-1996 flunked a cost benefit test. Getting rid of those regulations would have increased the size of the economic pie by $300 billion." End stop. The rest of the piece is spent detailing his proposals for "reform." Robert W. Hahn and Robert E. Litan, Putting Regulations to a Test, Wash. Post. A23 (Jul 30, 1997). Hahn's primary analysis is only slightly more nuanced. He offers numerical ranges to reflect different assumptions, but his ranges reflect only the impact of different values for life values and discount rates. Government's Numbers (2000), *supra* note 13, at 46, 59. In fact, Hahn's only acknowledgment of uncertainty is in reference to: (1) the discount rate (within the range of 3-7 percent), (2) the appropriate base year (he chooses 1996 but admits he had trouble choosing), and (3) two sentences buried in a section devoted mainly to other matters and labeled "The relative efficiency of regulations." In these sentences he acknowledges that: "technological advances and scientific discoveries may reveal that agencies understated the benefits of existing rules," and "variation in the assumptions agencies and program offices use to estimate benefits and costs affects the results of such analytical exercises." Id. at 54. Morrall, Graham and Tengs offer no sensitivity analysis whatsoever.

249. See, e.g., Petroleum Refinery Sludge Rule, 55 Fed. Reg. 46,354, 46,391- 46,393 (1990) (predicting range of cancer case avoidance, disclosing uncertainty in non-cancer benefits, and reviewing factors that tend to overestimate and underestimate benefits); Worker Protection Standard for Agricultural Pesticides, 57 Fed. Reg. 38,102, 38,145 (1992) (providing range of costs and benefits, and description of unquantifiable benefits); Seafood Safety Rule, 60 Fed. Reg. 65,096, 65,185 (1995) (same).

250. Annapolis Principles, *supra* note 111, at 10 ("Best estimates should be presented along with a description of the uncertainties"). OMB's guidelines treat the issue much more fully:

"The principles of <u>full disclosure</u> and <u>transparency</u> apply to the treatment of uncertainty in developing risk, benefit and cost information – just as it does with the other elements of economic analysis. You must identify data, models, and their implications for risk assessment in the risk characterization. You must also explicitly

66

scorecards do not deny the validity of this canon. The problem is that they do not implement it.

The reasons for such omissions are not hard to imagine. Proper disclosure of ranges to reflect uncertainties would render many interventions numerically indeterminate: either because the high end of the cost range would overlap the low end of the benefit range – or vice-versa – or because important, unquantified costs or benefits would vitiate the relevance of numerical ranges. In either event, scorecards would no longer be able to provide a clear "score" for the regulation in question. They would cease, in essence, to be scorecards. That is why this Article suggests that the obfuscation of uncertainty is an inherent – not merely a contingent – defect of scorecards.

D. *Assuming efficiency is all that matters*

The discussion so far has assumed something that scorecards (and most economists) regularly take for granted: that "good" regulations are those that maximize net benefits or cost-per-life-saved as determined by experts. While this Article generally does not contest this crudely utilitarian premise, for the reasons stated in the Introduction, the deeply problematic nature of that premise should not go entirely without mention.

One major difficulty with assuming that the right policy is one that maximizes aggregate net benefits may be illustrated with a simple example. Automobile accidents kill over 40,000 Americans – about twelve times the death toll of the World Trade Center bombings – *every year*.[251] It is highly likely that a cross-section of experts assigned to consider the issue would agree that at least some of the many billions of dollars now being spent searching diaper bags and grandmothers in airports would actually save more lives per dollar if diverted to programs for improving auto safety. Yet this is virtually unthinkable in the current climate. The American public is accustomed to auto risks and terrified of terrorism. We want everything done that can be done to stop the latter. Other threats, at other times, likewise have dominated public consciousness for a period leading to rather expensive public responses – cryptosporidium, AIDs, toxic waste in basements, microwave towers, cancer. Experts have known for over a

250. (...continued)
identify and evaluate the inferences and assumptions chosen and assess the effects of these choices on the analysis."
OMB Guidelines, *supra* note 87, at 14-15. OMB also confronts, and squarely rejects, the misguided practice – ubiquitous in scorecards – of taking point estimates (usually the mid-point of a range) as "best" estimates without knowledge of underlying probability curves: "If the uncertainty in the estimates – for example, fundamental scientific disagreement or lack of knowledge – prevents construction of a scientifically defensible probability distribution, you should describe the benefits and costs under plausible alternative assumptions." Id. at 15.

251. Following are motor vehicle death statistics for the period 1991-1998, the latest year for which complete data are available:

Year	1991	1992	1993	1994	1995	1996	1997	1998
Deaths	43,536	40,982	41,893	42,524	43,363	43,649	43,458	43,501

Source: National Center of Health Statistics, Historical Tables on Leading Causes of Death 1900-1998, available at www.cdc.gov/nchs/data/lead1900_98.pdf.

decade that they ranks risks differently than the public.[252] The question is, so what? What follows from the fact that public fears and wishes are, at times, "inefficient" in the opinion of experts? To the extent that there is psychological value in minimizing public fear (as opposed to risk) – or democratic virtue in accountability to the public – then the best regulation may not always be the most cost-effective one.[253]

By the same token, the best regulation is not necessarily the one that caters most to the public fear *du jour*. A tension exists between the dueling goals of rationality, and democracy, in regulation. One way to resolve it may be through better educating the public. Another way might be through better educating experts about the things that matter to the public. The optimal strategy for managing that tension may well depend on the facts of each particular case. But if that is so, it is certainly problematic to assume, as scorecardists do, that accountability is weightless in the scales, and that public risk and benefit perceptions are always of zero significance when they differ from those of the "experts."

Besides ignoring public preferences, the simplistic utilitarianism of scorecards also inherently occludes all questions of individual rights. All agree that society may not condemn an innocent individual to certain death, even for a monetary gain in excess of the monetary value of a statistical life. That is why those who defend the valuation of statistical lives take such pains to point out they are assigning a monetary value only to small increments of risk – increments that some individuals have shown themselves willing to assume in marketplace behavior.[254]

It is necessary, however, to follow this concession to its logical conclusion. If society may not impose certain death on an individual, then it follows that society also may not impose a very high likelihood of death on an individual.[255] In other words, bringing a sense of rights into the picture indicates, at a minimum, that there is a threshold of risk which government may not allow one set of individuals to impose upon another through market

---

252.   See Leslie Roberts, Counting on Science at EPA, 249 Science 616 (1990) (reporting results of two EPA task forces which found that agency experts rank environmental risks very differently from the American public). For the original reports, see Unfinished Business, *supra* note 74; Science Advisory Board, U.S. Environmental Protection Agency, Reducing Risk: Setting Priorities and Strategies for Environmental Protection (1990).

253.   Finkel has also adduced a number of plausible reasons why the subjective comparative risk assessments of experts may not necessarily be more plausible than the heuristic judgements of lay persons. See Adam M. Finkel, A Second Opinion on an Environmental Misdiagnosis: The Risky Prescriptions of Breaking the Vicious Circle, 3 NYU Envt'l L J 295, 318-321, 328-331 (1995).

254.   See, e.g., Fatal Tradeoffs, *supra* note 15, at 19-20; Hahn, Government's Numbers (2000), supra note 13 at 39 n. 23. For insightful discussions of the difficulty cost-benefit analysts face in accommodating rights-based concerns, see Tribe, Analysis or Ideology, *supra* note 35; Kelman, *supra* note 104; Heinzerling, Pricing the Priceless, *supra* note 38.

255. This observation leaves aside, for present purposes, the moral issues raised by a military draft, or absence thereof.

or non-market activity, whatever the social gain.[256] Likewise, our system of contract and tort law recognizes individual rights by limiting the ability of an individual to impose physical and economic losses on others, without actual compensation. Finally, the present generation may be seen as holding certain ethical obligations to future generations.[257]

In principle, as seen above, rule- or project-specific cost-benefit analysis can meet these democratic and right-based concerns by detailing the impact of each regulation on the distribution of risk and loss, and by allowing ethical considerations to trump the numerical analysis whenever the physical or economic impact crosses a certain threshold.[258] But purely quantitative analyses cannot do so, and neither can strictly numerical scorecards.

***

This Part has shown that the Morrall, Tengs/Graham and Hahn scorecards ignore all considerations of public preference and individual rights. They also violate basic principles of cost-benefit analysis which require consideration of significant, unquantified costs and benefits; consideration of distributive and cumulative impacts; and full disclosure of the uncertainties, sources of uncertainty, and the consequences of varying important default assumptions. Moreover, numerical scorecards cannot *possibly* conform to these basic principles of sound cost-benefit analysis and still do what scorecards claim to do, which is to compress a vast range of human experience into a few small numbers. While regulatory scorecards may be faulted on political and ethical grounds, it is important to understand that scorecards fail to pass muster even by the interior logic of economic cost-benefit analysis itself.

III. TOWARDS A RESPONSIBLE APPROACH TO GRADING GOVERNMENT REGULATION

Before any traveler who is lost can find his way home, he must first come to the realization that he is lost, and that he needs to seek direction. Before any problem can be fixed there must come, first, a recognition that there is a problem that needs fixing.

This Article is not, fundamentally, about furnishing remedies but about diagnosing a serious problem of evidence and proof at the heart of the regulatory reform movement – a problem that arises from the failure of studies which attempt to reduce regulatory analysis to a few summary numbers. Nonetheless, the preceding discussion does yield a number of affirmative insights into how regulatory performance ought to be evaluated, if not by simplistic scorecards. This Part pulls together those insights.

---

256. Congress has expressly recognized this fact in passing statutes that require EPA, for example, to regulate residual emissions of any toxic air pollutant causing a risk of more than one in a million to the "the individual most exposed to emissions from a source or category." See Clean Air Act, § 112(f)(2)(A), codified at 42 U.S.C. § 7412(f)(2)(A).

257. For the leading discussion of inter-generational equity see Edith-Brown Weiss, In fairness to future generations: international law, common patrimony, and inter-generational equity (1988).

258. See discussion *supra* Section II.B.

Section A deals with the implications for agency analysis of individual rules. Section B addresses the implications of this Article for the evaluation of regulatory performance overall.

A. *Implications for agency analysis*

Some will, no doubt, be tempted to find in the shortcomings of scorecards another argument for rejecting cost-benefit analysis *per se*. Such a reaction is especially understandable given the similarity of the scorecard abuses documented in this Article to those that other scholars have criticized in the analysis of individual rules over the last three decades.[259] As Professor McGarity asks, in a recent essay, why continue a practice that has proven itself over the years notoriously prone to abuse?[260]

Despite the considerable force of McGarity's argument, I do not go so far so to recommend the wholesale rejection of cost-benefit analysis at this point, for three reasons. First, cost-benefit analysis is a *fait accompli*. So long as millions of Americans (and a majority of the House and Senate) are concerned with the rationality of government regulations, they will continue to demand cost-benefit analysis as a way of addressing their concerns.

Second, cost-benefit analysis, at least in theory, fills a gap that other approaches leave open. Technology-based standard-setting, for example, begs the question of whether the "best available" technology is safe enough, or whether another approach would be much cheaper, or pose fewer risks of some other kind. Cost-benefit analysis offers a theoretical framework for addressing such questions in an orderly way.[261]

Third, and most important, the analysis of this Article neither supports nor refutes broad conclusions about the practice of cost-benefit analysis *per se*. This Article has focused on multi-rule scorecards which, as seen, raise particularly acute and inherent difficulties.[262] Though the deficiencies identified in this Article in connection with scorecards do not inspire much

---

259. See, e.g., Thomas O. McGarity, A Cost-Benefit State, 50 Admin. L. Rev. 7, 50-78 (1998); Shapiro and Glicksman, *supra* note 99; Driesen, David M., The Societal Cost of Environmental Regulation: Beyond Cost-Benefit Analysis, 24 Ecol. L. Q. 545 (1997); Lisa Heinzerling, Markets for Arsenic, 90 Geo. L. J. 2311 (2002); Pricing the Priceless, *supra* note 38; Howard Latin, Ideal v. Regulatory Efficiency: Implementation of Uniform Standards and "Fine-Tuning" Regulatory Reform, 37 Stan. L. Rev. 1267 (1985) (arguing that ideally efficient reforms need to meet real world tests of practicability, and that technology-based regulation often does this better than cost-benefit analysis).

260. As McGarity puts it, rather bluntly, in responding to Professor Sunstein's defense of cost-benefit analysis, "It is critical to understand that many of the "experts" to whom Professor Sunstein would assign the important task of "objectively" assessing and monetizing regulatory benefits are not fair-minded scholars like Professor Sunstein, but self-promoters . . . many of whom have devoted their careers to criticizing health, safety, and environmental regulation." Professor Sunstein's Fuzzy Math, *supra* note 71, at 2369.

261. The question is a close one. McGarity, Shapiro, Latin and others have argued with considerable force that technology-based regulation may often be the most efficient and practical approach to regulation in the face of large uncertainties about regulatory costs and, especially, benefits that responsible analysis often reveals. For an excellent discussion of these issues, see Sidney A. Shapiro & Thomas O. McGarity, Not So Paradoxical: The Rationale for Technology-Based Regulation, 1991 Duke L. J. 729 (1991); and Latin, *supra* note 259.

262. See *supra,* Part II.

confidence in cost-benefit analysis as a genre, conclusively proving invalidity of the latter would require a broader critique than this Article undertakes.

Though this Article does not take a position on cost-benefit analysis overall, the preceding analysis does suggest several important recommendations for the conduct of cost-benefit analysis at the agency level, assuming it continues to be done:

1. The evidence refutes the widespread belief of regulatory skeptics that agencies routinely over-estimate the benefits of regulations they propose or enact.[263] While agencies may, in some cases, adopt quite conservative assumptions in assessing cancer risks and cancer reduction benefits, non-cancer health and ecological benefits are frequently relegated to a few perfunctory sentences – or bury important data about benefits in unpublished regulatory impact assessments that are then incorporated by reference in the final rule.[264] This is a serious disservice to public understanding of regulatory matters. Even in cases where the data do not permit full quantification of regulatory costs or benefits, agencies need to do a much better job of explaining the significance of costs and benefits (particularly unquantified costs and benefits) narratively, and the reasons underlying the agency's determination that the benefits justify the costs.[265]

2. While agencies cannot avoid valuing risk to human life (at least implicitly), the life and health values in current use are empirically questionable, and probably too low. At a minimum, adjustments should be made to reflect the involuntariness of certain risks, the effect on risk preferences of income distribution and growth, and heterogeneity of risk tolerance.

3. Ultimately, agencies should consider simply abandoning the pretense that the monetary values assigned to non-monetary impacts are numerically rigorous and scientifically based They are not, nor need they be. Government agencies have a rightful normative function which they should exercise openly – without seeking to conceal their exercise of discretion behind a gauzy veil of numbers.[266]

4 When conducting cost-effectiveness analysis (which looks at cost-per-life-saved), agencies should cease the semantically misleading practice of discounting the number of lives saved.[267]

5. All analyses which involve monetizing and/or discounting non-monetary values should include a clear and prominent statement of the *physical* costs and benefits of the rule – the risks created as well as the lives

---

263. Contrast Morrall, supra note 8 at 25 ("regulatory agencies . . . tend to over-state the effectiveness of their actions), Hahn, Government's Numbers (2002), supra note 13 at 35 ("agencies are likely to overstate net benefits), and Nichols and Zeckhauser, Albert L. Nichols & Richard J. Zeckhauser, supra note 80 (discussing how conservative risk assessment distorts regulation by over-stating benefits), with agency elision of benefits of rules discussed in Section II.A. *supra*.

265. See *supra* Section II.A.1.

266. Id.

267. See *supra* Section I.E.

saved, illnesses avoided, and ecological harms prevented or remedied – along with the timing and distribution of such costs and benefits. Readers can then reach their own judgment as to whether benefits justify costs, without the loss of information that results from altering primary data by assumptions supplied by economists.[268]

6. Agency cost-benefit assessments should include a full discussion of all relevant uncertainties. These uncertainties will, in many if not most cases preclude simple, numerically determined declarations about whether benefits will exceed costs. Rather than feeling obligated to pretend to a certainty that does not exist, agencies should be prepared to acknowledge such indeterminacies when they arise. The presence of large uncertainties often counsels incremental decision-making through flexibility mechanisms such as variances, waivers, and preservation of later implementation discretion. These mechanisms are already routinely employed. Agencies should carefully analyze the potential significance of such mechanisms in characterizing the costs and benefits of each rule. Agencies also should incorporate – as they now do not – a discussion of the consequences of erring in the direction of under- and over-regulation, respectively.[269]

7. Retrospective studies, though difficult, are indispensable tools for: capturing the impact of waivers, variances, and other uses of official discretion; detecting errant predictions of costs and benefits; identifying important sources of estimation error; calibrating *ex ante* estimates; and, most of all, identifying needed changes to rules.[270]

8. If rational priority-setting in regulation is the goal, then it seems clear that cost-benefit analysis cannot be limited to screening final regulations. Agencies should also use the instrument for identifying risks that are not now regulated but which ought to be – even (and especially) if they lack statutory authority to address the risk at the time of the assessment. Setting agendas for future legislative initiatives has long been recognized as a vital function of cost-benefit analysis.[271]

---

268. Much of the current controversy over life valuation and discount rate might have been avoided (or marginalized) by this simple expedient, which OMB has endorsed. See *supra* Section I.E.

269. See Sections I.C. and II.C.

270. Indeed, the idea that a single *ex ante* estimate could provide an accurate picture of regulatory costs and benefits in perpetuity is absurd on its face. Yet that is the proposition implicit in the current practice of relying on a single *ex ante* estimate for data on "the" costs and benefits of each rule. See discussion in Section I.C.

271. The current OMB/OIRA director, John Graham, has made a start in the right direction with a new policy of encouraging agencies to identify new opportunities for cost-effective regulation. See Nakashima, *supra* note 4 (noting that Graham has created the "prompt letter" which urges agencies to issue rules in areas that appear to be cost-effective). It remains to be seen how far this initiative will extend in practice.

If OMB really intends to make the initiative meaningful, it should: (1) instruct agencies to include a "regulatory opportunities" section as part of their strategic plans; (2) include an overview of regulatory gaps in OMB's annual report on costs and benefits of legislation; and (3) propose legislation that would require agencies and/or OMB to prepare periodic reports on *gaps* in regulatory programs that present real regulatory needs and offer cost-effective regulatory opportunities.

A new focus on regulatory opportunities may not be as controversial, or unlikely in the present climate, as one might tend to assume. Indeed, identifying favorable regulatory

9. Requiring agencies to perform more – and more thorough – cost-benefit analyses will be expensive. That is not an objection to the requirement. It is simply an objection to imposing the requirement as an unfunded mandate. By any reasonable reckoning, the costs of responsible analysis are trivial compared to the economic, human and ecological stakes involved in social regulation. If getting the analysis right requires doubling or tripling agencies' analytical and regulatory budgets, so be it. Congress must realize that in regulation, as elsewhere, "you get what you pay for."

B.   *Implications for comprehensive evaluations of regulation*

While strengthening the quality of single-rule analysis is an important first step, it is not the end of the road. There remains the issue of how best to evaluate regulatory performance overall. While full treatment of this issue lies beyond the scope of this brief concluding section, the broad contours of an appropriate approach may be inferred from the critique this Article has offered.

The central message of this Article is that while responsible cost-benefit analysis may reveal clear successes and failures in some cases, it is also certain to yield a significant category of ambiguous cases, in which existing data simply do not support an objective determination of whether the net benefits of the regulation are positive, or not. Policy-makers and the public generally should defer to agencies in ambiguous cases, just as courts are already instructed to do.[272]

Once the clear successes and clearly ambiguous cases are subtracted from the tally, what remains will be a smaller group of clear or likely regulatory failures – situations in which it appears that neither the health nor the ecological benefit can plausibly justify the sums expended in pursuit of it; or in which more protection could have been achieved at less cost through greater flexibility or better regulatory design; or in which what should have been a cost-effective regulation did not materialize. These are the cases which ought to attract the attention of scholars and policy-makers, whatever their ideological bent. But these cases ought to attract attention in a different, and more constructive, way than they do now. Rather than merely serving as illustrations for sweeping pro- or anti-regulatory polemics aimed at wholesale "reforms," these cases should first stimulate a three-part empirical investigation.

---

271. (...continued)
opportunities may present a win-win-win opportunity for agencies, public interest groups, and regulated interests. For agencies and public interest groups, closing regulatory gaps offers obvious public interest benefits. But currently regulated entities stand to gain as well: to the degree that agencies identify, and are given authority to regulate, the highest priority risks (including those now protected by gaps in agency jurisdiction) agencies may be less prone to try to extract the last ounce of protection from the sources currently within their control. See National Academy of Public Administration, Setting Priorities, Getting Results: A New Direction for the Environmental Protection Agency 61-66 (1995) (describing how EPA's lack of jurisdiction to regulate radon in indoor air may have led the agency to focus excessively on regulation of radon in drinking water, which EPA had jurisdiction to regulate).

272.   See Ethyl Corp. v. EPA, 541 F.2d. 1 (D.C. Cir. 1976) (calling for judicial deference to agencies when facts are ambiguous), and Chevron, U.S.A., Inc. v. Natural Resources Defense Council, Inc., 468 U.S. 1227 (1984) (calling for deference to agency interpretations when statutory text is ambiguous.)

Initially, there should be a serious effort to obtain broad consensus on the facts of each case and on the characterization of the case as one of regulatory failure through over-regulation, under-regulation, or mis-regulation. Then, if a failure is established, there should be a concerted effort to determine whether the failure is typical, or aberrational. Finally, if the failure is found to be of a programmatic nature, there should a sustained inquiry into causes – whether statutory, political, or bureaucratic – so that reform efforts can be focused on the root causes of failure.

The difference between the approach to regulatory reform described above and the way now taken is, roughly speaking, the difference between pragmatic/inductive/empirical and deductive/polemical/anecdotal approaches. The polemical approach in current use certainly has its advantages: it offers ease of analysis, powerful rhetoric, and an easy path to broad and clear conclusions which rigorous empiricism might confound. The principal advantage of the empirical approach, on the other hand, is simply that it offers the only reliable means of finding the facts about regulation – and the only conceivable route of escape from the vicious cycle of ideological claim and counter-claim in which the regulatory debate is now mired. Everyone agrees that regulation should be based on "sound science." Yet, as this Article has shown, much of regulatory debate itself is being waged on profoundly un-scientific – indeed, pseudo-scientific– terms, using unverified anecdotes or unsupportable and misleading numbers. The obvious solution is to hold critics and defenders of regulation to the same standard of rigorous empiricism that all demand of regulators themselves.

Who would do the investigating? It seems doubtful that either existing agencies or their entrenched critics in think tanks have the credibility, the independence and detachment needed to do the job effectively, and credibly, themselves. Indeed, think-tanks produced two of the three shoddy studies this Article has critiqued.

Although academia might fill this investigative role, it seems unlikely (to this author) that academics will find it in their own professional interest to devote to the humble, un-prestigious task of empirical research the time and effort needed to implement the methodical approach just described over a sustained period.[273]

The only clear, remaining alternative is to establish a new body to act as a sort of external "ombudsman" in investigating allegations of regulatory failure, reporting causes and recommending remedies.[274] While this may seem an expensive and elaborate response, it can hardly be considered disproportionately so. If it is true that billions of dollars are wasted each year due to over- and under-regulation, then surely it would be cost-effective to authorize a few million dollars a year for an bipartisan team of researchers to investigate allegations of systemic failures, establish the facts, and recommend suitable remedies.

CONCLUSION

---

273. See McGarity and Ruttenberg, *supra* note 67, at 2058.

274. For a discussion of types, responsibilities and issues raised by various types of ombuds, see American Bar Association, Standards for the Establishment and Operation of Ombuds Offices: ABA Policy Adopted August 2001.

Regulatory scorecards have played a major role in shaping contemporary views of the administrative state. They come from prestigious sources, claim to be comprehensive and objective, and reach sensational conclusions. The result has been an extraordinary degree of influence for both the studies and their authors.

Yet this Article has shown that, in fact, these scorecards:

• alter agency numbers in undisclosed and arbitrary ways;
• draw on biased samples of regulation;
• under-value the benefit of reducing risk to life and health;
• misrepresent *ex ante* guesses as actual cost-benefit measure-ments;
• falsely assume that regulations will never be eased or modified;
• disregard major categories of quantified and monetized benefits;
• disregard all unquantified costs and benefits;
• ignore important non-linearities of risk and risk preferences, as well as cumulative and distributive impacts;
• assume that savings from regulations foregone will be re-directed to save lives, even though no mechanism for accomplishing such a re-direction exists; and
• conceal important uncertainties, as well as virtually all the omissions and alterations discussed above.

In short, the three most widely-cited and influential scorecards underlying the regulatory reform movement – studies issued by AEI-Brookings, the Harvard Center for Risk Analysis, and a senior OMB economist – are revealed to be, on close inspection, well-meant but deeply flawed analysis which fail to prove their own conclusions.

In a brilliant monograph entitled, The Rhetoric of Reaction, A.O. Hirschman describes the tried and effective rhetorical devices by which very appealing goals – such as equality, self-determination, or, by extension, protecting health, safety or the environment – may be assailed or ridiculed indirectly when frontal assault is impossible in view of the popularity of the goals.[275] One such rhetorical device is the "perversity thesis" whereby the skeptic argues that pursuing the goal in question will produce unexpected or disproportionate costs and may, in fact, move society *away* from the goal. Scorecards – with their focus on the costs imposed by government intervention, and lives supposedly sacrificed thereby – are perfect examples of the perversity thesis applied to regulation. That, in itself, does not make them wrong: truth can be trite. Nor do I mean to suggest that Hahn, Morrall, and Graham prepared their scorecards with intent to mislead. I have found no evidence of any such motive.

Nonetheless, when studies are shown to be blatantly untrue, Hirschman's analysis does help explain why deeply flawed studies are received so uncritically, and why they are circulated so enthusiastically, by those who disdain regulation. Scorecards draw on a tradition of rhetoric – the rhetoric of reaction – that has been used, and proven effective, for centuries.

This is not say that the American regulatory system is perfect, rational, or even good. This Article reaches no conclusion on that issue and certainly

---

275. Albert O. Hirschman, The Rhetoric of Reaction: Perversity, Futility, Jeopardy (1991).

finds plenty of room for improvement in agency analyses. The point is not that all regulations are rational, but that critics have only pretended to prove that our regulatory system is pervasively irrational.

Arriving at valid conclusions about the cost-benefit rationality of our regulatory system is going to require much more than has been done so far. It will require closely investigating the facts of alleged regulatory failures (including failures to regulate) one intervention at time, with careful regard to unquantified variables, uncertainties, cumulative impacts, and distributive concerns. And it will require, in cases where failure is found, patient empirical inquiry to determine whether the problem is typical or aberrational, and to identify its root causes.

Meanwhile, we should be wary of spectacular numerical claims that purport to show the systemic irrationality of government regulation from a cost-benefit perspective. For the tests that claim to show this are invalid.

Annex A
Morrall Table

Regulation	Year	Agency	Status*	Initial Annual Risk**	Annual Lives Saved	Cost Per Life Saved (thousands of 1984 $)

189	SUMMARY

				Dollar Amount	
191	Funds spent on "inefficient" interventions				% of total base $
192	-- threshold of effic. at $8m/life			$2,642,043,049	12%
193	-- threshold of effic. at $7m/life			$16,956,699,312	79%
194	-- threshold of effic. at $5m/life			$17,070,185,847	80%
195					% of total realloc $
196	Funds made available for realloc by fully funding negative cost interventions			$9,584,144,277	54%
197					
198	Funds supplied by reducing or eliminating costly interventions			$8,108,361,097	46%
199					
200	Add'l lives saved by realloc. as per 1981 NHTSA study			12,487	

Annex B-2

Table 1[1]
Key additional life savers in re-allocation

Row # (Annex B-1)	Description (#, date of estimate)	% Imp. in Baseline	Add'l Lives Saved in Reallocation
22	Continuous (vs. nocturnal) oxygen for hypoxemic obstructive lung disease (#709, 1980)	49%	22,950
20	Influenza vaccine for all citizens (#455, 1981)	13%	19,205
41	Full (vs 50%) enforcement of nat'l 55 mph speed limit (#175, 1981)	3%	3,502
50	Radon remediation in homes with levels >8.11 pCi/L (#1267, 1991)	12%	2,855[2]
16	Media campaign to increase voluntary use of seatbelts (#175, 1981)	15%	2,805
44	Alcohol safety program for drunk drivers (#175, 1981)	8%	2,375
14	Mandatory seat belt use and child restraint law (#175, 1981)	85%	1,537
37	Driver & passenger non-motorized automatic (vs manual) belts in light trucks (#1089, 1990)	5%	1,185[3]
13	Brady method screening for group B streptococci colonization during labor (#1220, 1990)	10%	1,107
	TOTAL		57,521

---

1. All data are derived from Graham/Tengs unpublished spreadsheet reproduced in Annex B-1.

2. Derived by subtracting 368 (number of lives saved in competing radon intervention - row 55) from 3,223 (lives saved in dominant radon intervention - row 50).

3. Derived by subtracting 103 and 16 (number of lives saved in competing seat belt interventions - rows 37 and 57, respectively) from 1,304 (lives saved in dominant intervention in cluster - row 37).

Table 2[4]
Key fund sources in re-allocation

Row	Description (#, Date of Estimate)	Funds Supplied for Re-allocation	% of funds re-allocated
	Total funds re-allocated	$17,692,505,374	100.0%
	Funds supplied by fully implementing negative-cost interventions	$9,584,144,277	54.0%
3	Ban residential growth in tsunami-prone areas (#1221, 1982)	$8,655,184,021	49.0%
4	1988 Safety Standard for concrete construction	$351,152,113	2.0%
6	Truss (vs. elective inguinal herniorrhaphy) for inguinal hernia in elderly patients (#148, 1977)	$317,196,000	1.8%
	Funds supplied by eliminating or reducing costly interventions	$8,108,361,097	46.0%
101	Ozone control for So. Cal (partial elim)	$4,233,074,235	23.9%
122	Flammability Standard for Children's Clothing	$1,029,138,693	5.8%
139	Construct sea walls to protect against 100-year storm surges (#1221, 1982)	$576,022,732	3.3%
84	Widen lanes on rural roads	$509,008,193	2.9%
138	Staff school buses with adult monitors (#1124, 1989)	$351,251,057	2.0%
